The fact that radical mastectomy does cure an appreciable proportion of patients who have axillary metastases should be apparent to any one. Taylor and Wallace³² in their latest (1933-1935) report of the end results in the Massachusetts General Hospital series stated that five year cures were obtained in 33.3 per cent of their patients with axillary involvement. About 60 per cent of all patients operated on have axillary metastases. The surgeon who does only a simple mastectomy wilfully forgoes the opportunity of five year cure in one third of these patients.

Worse than this is the fact that in the remaining 40 per cent of patients who do not have axillary metastases a simple mastectomy gives nowhere near as good a chance of cure as a radical mastectomy. In simple mastectomy the area of skin sacrificed is small, and the flaps are so thick that a good deal of mammary tissue which may harbor carcinoma remains on them. The pectoralis major muscle is not removed. This muscle, or the fascia overlying it, is frequently involved by carcinoma when the lesion is situated deeply in the breast.

Unfortunately, the vogue of simple mastectomy which might be expected to wane in time as the advantages of thorough surgery become more widely known, has recently received a strong impetus from the University of Edinburgh. In this academic circle with a long tradition of sound medicine and good surgery Dr. R. McWhirter³² has convinced his colleagues that simple mastectomy supplemented by postoperative radiotherapy gives results that are superior to radical mastectomy. His argument rests solely on the statistical evidence that the combination of simple mastectomy and radiotherapy has given a five year survival rate of 50.1 per cent, as compared with a survival rate of 44 per cent in an earlier series of cases in which treatment was by radical mastectomy alone. The weakness of his argument is apparent from the fact that in his series of cases in which treatment was by radical mastectomy alone the local recurrence rate was 39 per cent. We know that such a high local recurrence rate means either that the cases are improperly selected for operation or that an insufficiently radical operation has been done—or both. McWhirter has not given the modern thoroughly radical operation a fair chance: it can give a five year cure rate higher than his five year survival rate. Moreover, all that we know of the effects of radiation on carcinoma

of the breast convinces us that most patients treated by simple mastectomy and postoperative radiation who survive will harbor viable carcinoma locked up in fibrosis, which eventually will reappear locally.

BILATERAL CARCINOMA OF THE BREAST

The development of carcinoma in the second breast following a successful operation for carcinoma in one breast is a manifestation of the disease which requires special mention, if for no other reason than to emphasize the fact that this is not as unfavorable a complication as might be supposed. We have seen a fair number of patients cured of their second carcinoma of the breast. Harrington,³³ who has reported the largest series of cases of bilateral disease, unfortunately failed to include survival rates following operation on the second breast, but he did state that the results may be very satisfactory. McWilliams³⁴ collected instances of bilateral carcinoma of the breast and worked out a five year survival rate of 21.1 per cent following the operation on the second breast. When both breasts are involved simultaneously the prognosis is much poorer.

In McWilliams' series 32 per cent of the patients had their second tumor within a year after the first one. There can be no assurance, however, that the disease may not develop in the second breast at any time during the remaining life span of the patient; Harrington recorded 1 case in which twenty-eight years elapsed between the two carcinomas. In the follow-up examinations of patients who have had carcinoma in one breast it is important always to examine the opposite breast with care, no matter how long a time has gone by since the disease originally appeared.

McWilliams calculated that in 5 per cent of women who get carcinoma of the breast it develops in both breasts, the disease occurring consecutively in 4.7 per cent and simultaneously in 0.2 per cent. Our own impression is that the incidence of involvement of the second breast will be found to increase as the thoroughness of the follow-up improves, and that it approximates 10 per cent. Perhaps half of these cases are examples of secondary involvement of the opposite breast late in the course of the disease in patients in whom the operation on the side originally involved failed to eradicate the disease locally. The internal mammary lymphatic pathway becomes blocked by metastases, and retrograde permeation of the lymphatics crossing the midline carries the carcinoma into the second breast. This is a regular event in carcinoma *en cuirasse*.

The important thing from the surgeon's point of view is to know whether the carcinoma in the second breast is a metastasis or local extension from the carcinoma in the first breast, or whether it is an entirely new carcinoma. If it is the former, cure is impossible and palliative radiation only should be given; if it is the latter, a second radical mastectomy is indicated. This question is sometimes difficult to decide. The best guide is the absence of local recurrence on the operated side and of distant metastases. If these evidences are not found it is more than likely that the second carcinoma is a new one: at least it should be treated as such.

LOCAL RECURRENCE

Comparison of the results of radical mastectomy in different clinics in terms of the cure rates is hardly worth while, because of the variations in the com-

pleteness of follow-up and in the statistical methods used. One surgeon reports five year survivals, not knowing how many of his patients have recurrence or metastases, while another reports five year clinical cures, including only those patients who he knows have been well since operation. One surgeon in determining his survival rate arbitrarily excludes from his compilation a large group of what he calls "indeterminate" cases, amounting to 30 per cent of his total number of primary cases, and calculates his survival rate only on the remaining 70 per cent. This, of course, gives him a favorable survival rate as compared with that of the surgeon who follows the statistical method recommended by the League of Nations Cancer Commission³⁵ and does not deduct a single case from the total number treated, every patient whose treatment was incomplete, or who died of intercurrent disease, or who was lost track of being counted as a failure. The League of Nations Commission to which I refer was a group of gynecologists who in 1929 drew up a comprehensive plan for the classification of the different forms of uterine cancer and laid down strict standards for the computation of the end results. This statistical method has been generally adopted in all the large gynecologic cancer clinics in Europe and America with the result that today truly comparable data regarding the different methods of treatment of uterine cancer are available. There is a great need of transposing these same methods for use in reporting the results of the treatment of carcinoma of the breast.

In weighing the results of radical mastectomy it might be argued that the surgeon cannot be held responsible for failure when the patient succumbs to distant metastases which gave no evidence of being present before operation. Our present methods of clinical investigation are simply not good enough to detect these latent distant metastases which are the cause of death in the overwhelming majority of patients who are not cured by radical mastectomy. In most of these unfortunate patients metastasis probably takes place some time before they come for treatment, rather than during operation. The surgeon innocently goes ahead with futile radical mastectomy because he has no way of knowing that the disease has already spread far beyond his reach.

The surgeon certainly is accountable, however, for local recurrence in the field of operation—that is, on the chest wall or in the axilla. Reappearance of the carcinoma here means either that he wrongly chose to operate, for radical mastectomy should not be attempted when the local disease is beyond cure, or that he did an inadequate operation.

Sometimes the former factor and sometimes the latter factor explains the high incidence of local recurrence. Rienhoff has stated that in Halsted's time, and indeed for long afterward at Johns Hopkins Hospital, no attempt to select operable cases was made—all were operated on. This is no doubt the main reason why Halsted's local recurrence rate was 31.9 per cent. Rienhoff³⁶ in 1932 reported that in a further series of cases at the Johns Hopkins Hospital the local recurrence rate rose to 39.7 per cent when the operative technic was changed only to the extent of removing less skin to allow plastic closure of the wound. Here the second

36. Lewis, D., and Rienhoff, W. F., Jr.: A Study of the Results of Operation for the Cure of Cancer of the Breast, Ann. Surg. 95: 336, 1932.

factor of a less radical operation would appear to have played a part.

Since Halsted's day a beginning attempt to select curable cases for operation has cut down the incidence of local recurrence somewhat in many clinics. Yet it has been our personal experience from studying the end results of radical mastectomy in the records of several hospitals that the more complete the follow-up data the higher the local recurrence rate will be found to be and that it is usually found to be distressingly high unless rigorous criteria of operability are followed in selecting the cases for operation. In the Presbyterian Hospital¹⁴ series of cases (1915-34) in which no definite plan of selection was followed, the local recurrence rate was 22.8 per cent. White,³⁷ who has been specially interested in the problem of local recurrence, reported an almost identical local recurrence rate of 22.6 per cent at the Roosevelt Hospital.

The surgeons who have succeeded in reducing the local recurrence rate materially below this level have accomplished it by strict selection of their cases for operation, aided to some extent by the thoroughness of their operative attack. Taylor and Wallace^{21c} at the Massachusetts General Hospital, where well defined criteria of operability have been developed, report local recurrence in 11 per cent of the cases in their latest (1933-35) study of end results. In my personal series of cases at the Presbyterian Hospital in which careful selection has been made of cases for operation on the basis of the criteria listed, and most of the operations performed by the resident surgeons, there was local recurrence in 12.5 per cent of the patients.

In tabulating the incidence of local recurrence in our series of cases we have been careful to include every case in which the disease reappeared in any form on the chest wall or in the axilla on the operated side. The distressing parasternal recurrences, which appear from the depths of the intercostal spaces close to the sternal edge and grow outward forming a firm poorly circumscribed mass beneath the skin, are included. These are not skin recurrences at all, but apparently develop from carcinoma emboli in the intercostal lymphatics at the point where they perforate the chest-wall accompanying the perforating vessels, or as the result of retrograde growth of metastases in the internal mammary lymph nodes. If this is the correct explanation of this type of local recurrence the thoroughness of the operation can have little bearing on its frequency, for no surgeon attempts to excise the intercostal tissues. In patients with such carcinoma emboli in lymphatics running in fascial planes and accompanying vessels at the periphery of the operative field it would seem logical to expect that some of the emboli would have escaped beyond the operative field. Clinical experience supports this supposition, for patients in whom these parasternal recurrences develop invariably prove to have distant metastases.

The surgeon may not be blamable for parasternal recurrences, but he cannot escape responsibility for the button-like recurrent skin nodules which are apt to appear along the scar line when an inadequate area of skin is removed. These develop, beyond all doubt, from carcinoma cells implanted by the surgeon's instruments as he manipulates or sutures the edges of the wound. The cases in which such recurrences appear are usually ones in which it is apparent that the operation was not truly a radical mastectomy at all, but a

sort of glorified local excision of the carcinoma. This kind of surgery is reminiscent of the surgical methods in Billroth's time, seventy-five years ago. He had 82 per cent of local recurrences.

The great majority of local recurrences appear within the first three years after operation, and a patient who reaches the five year mark is fairly safe from this hazard. In rare instances local recurrence appears many years after operation: Woolsey³⁸ collected reports of a series of such late local recurrences including 1 instance in which the disease recurred locally after twenty-five years.

PALLIATION WITH RADIOTHERAPY

When the surgeon decides, after careful study of his patient, that her carcinoma of the breast is locally inoperable he may send her to a radiotherapist for palliative radiation. With suitable treatment the local lesion can be controlled for a varying period of time—in many instances until the distant metastases get beyond control. Lenz³⁹ has been treating inoperable carcinomas of the breast with ever increasing amounts of roentgen rays, and has achieved striking palliation with these larger doses. The tumor of the breast is treated through five portals, and receives a tumor dose of 6,000 r or more. The axillary nodes receive a similar dose through three portals. Such large amounts of radiation can be administered safely only in small daily doses of 100 r to each of two or three fields. Ten patients among a total of 31 that Lenz has treated by this method have survived from seven to ten years. The morbidity of this therapy is considerable, and Lenz has emphasized that it should be reserved for inoperable cases, surgery being preferable in operable cases.

Carcinoma of the breast metastasizes very widely. In Warren and Witham's⁴⁰ series of 162 autopsies in cases of carcinoma of the breast there were only 8 cases in which metastases were not found, while in each of the remainder an average of five organs or tissues were involved. The sites of metastasis in their relative order of frequency were:

Distant lymph nodes.....	116
Lung	94
Liver	88
Bone	69
Skin	61
Pleura	56
Adrenal gland	50
Spleen	23
Peritoneum	21

Radiation is useless in some of these forms of metastatic carcinoma of the breast, particularly those in the abdominal viscera—the liver, spleen and peritoneum. Irradiation of widespread pulmonary metastases is not worth while, but if the metastases are limited to one relatively small area in the periphery of one lobe where a tumor dose of as much as 2,000 r can be given, temporary palliation may be obtained. In pleural metastasis temporary palliation occasionally results. Metastatic carcinoma in the brain or spinal cord, as Lenz and Freid pointed out, is usually secondary to advanced involvement of the skull or vertebrae, and at this stage radiation is of little help. Metastatic nodules in the skin usually regress promptly with adequate radiation. The disease can be held in check in the supraclavicular lymph nodes in most cases. The distressing symptoms

due to increased mediastinal pressure from metastases in mediastinal lymph nodes can be relieved temporarily.

Radiation finds its greatest usefulness in palliation of the pain caused by metastases in bone. The control of this symptom is one of the most important problems in carcinoma of the breast, for these lesions in bone often progress slowly and cause great distress.

The lumbar vertebrae and pelvic bones are the commonest sites of bone metastasis, perhaps because in these bones the wide sinusoids of the marrow spaces are a good harbor for emboli in the blood stream. Lenz and Freid⁴¹ reported the anatomic distribution of the bone metastases in 81 autopsied cases as follows:

Site	Percentage of Cases
Pelvic bones	62
Ilium	37
Ischium	58
Pubis	56
Spine	50
Cervical	13
Dorsal	40
Lumbar	57
Sacral	38
Femur	54
Ribs	39
Skull	35
Humerus	27
Scapula	16
Clavicle	14
Tibia	3
Sternum, radius, ulna, fibula, bones of the hands and feet each	1

Pain in the back or pain radiating down the thigh in a patient who has had carcinoma of the breast should at once suggest the presence of metastases in the spine or pelvic bones. The pain is at first not severe and is usually felt when the patient gets up from bed or from a chair, or when she jars her spine as in missing her step. For a while she continues to be perfectly comfortable when she lies quietly in bed. The discomfort on motion steadily increases, however, until the patient finds it impossible to get about.

The pain caused by these metastases in the vertebrae is probably due, at least in the beginning, to increased pressure or tension on the periosteum of the vertebrae rather than to direct involvement of the posterior nerve roots themselves. The pain is referred to the segment of the trunk or leg corresponding to the particular posterior roots which supply the periosteum of the involved bones. Thus metastases in the lumbar vertebrae may cause pain radiating down the leg in the distribution of the sciatic nerve.

For some inexplicable reason bone metastases are painless in certain few patients. Their bones may be riddled with disease before its existence is discovered, sometimes as the result of a pathologic fracture.

In a good many instances local tenderness develops over bones containing metastases. This is particularly true of rib metastases. Sensitiveness to sharp percussion is often present over involved vertebrae.

Pain is an indication for roentgen examination of the skeleton in a patient who has had carcinoma of the breast. If the clinical observations are sufficiently suggestive roentgen treatment should be started, even though the roentgen examination fails to show definite metastases. Patients with metastasis have often been condemned to suffer for months because clinicians relied on the roentgen observations rather than on sound clinical judgment. The difficulty of distinguishing early roentgenographic changes due to metastases from those of arthritis is too great to give the roentgen evidence

much weight. Moreover, as Lenz and Freid⁴¹ have pointed out, pain may precede the demonstrable roentgen changes by as long as twelve months.

In the great majority of patients with bone metastases roentgen treatment gives definite relief of pain. In some the relief lasts only a few months, but in others it may last two or three years, the patient being restored to a relatively normal life meanwhile. Since further radiation is eventually required in most cases it is wise to give only a moderate amount the first time. Of course when only one small area is involved, as for instance a single vertebra, a larger dose is justified.

The bone lesions thus treated show a varying degree of sclerosis. When the metastasis is limited to a single collapsed vertebra it may calcify in a truly remarkable way. Pathologic fracture of long bones, however, usually do not unite.

It is important to give the bone lesions rest and support during radiation and for some time following the completion of the treatment, in order to give an opportunity for fibrosis and recalcification. With metastasis in the spine this is best achieved with bed rest for a month or so and the wearing of a brace for a time afterward. Unfortunately many patients have to drag themselves in and out of the clinic as outpatients while receiving their radiation because they cannot afford hospitalization.

HORMONAL PALLIATION

The last few years have seen the evolution of a new method of influencing the course of carcinoma of the breast by changing the hormonal balance in the patient.

It was begun by the Glasgow surgeon Beatson.⁴² The observation that mammary function is dependent on ovarian influences both in animals and human beings prompted him in 1896 to try the effects of oophorectomy in women with cancer of the breast. He was impressed by occasional striking palliation from the procedure.

The operation was taken up by several English surgeons, with the result that by 1905 Mr. H. Lett⁴³ was able to collect reports of results in 99 inoperable cases of carcinoma of the breast. Seventy-five of these patients were under 50 years of age. In this group 29.3 per cent were reported to have shown considerable though temporary improvement, chiefly of superficial lesions.

Beatson himself, reporting his further experiences with the operation in 1911,⁴⁴ was less enthusiastic. He had narrowed the indications for the operation down to a comparatively small group of patients who had not reached the menopause and whose disease was not acute. In these the favorable effects were temporary and chiefly concerned cutaneous and subcutaneous nodules.

The majority of surgeons remained unconvinced of the value of oophorectomy in carcinoma of the breast, and in the enthusiasm for radiation treatment which came onto the scene during the next decade, Beatson's operation was given up.

The idea was revived again in the early 1920's by Wintz at Erlangen and by Ahlbom in Stockholm, who suppressed ovarian function by irradiation. Wintz⁴⁵

claimed good results, but Ahlbom⁴⁶ was unable to find any definite proof of the value of the treatment when he surveyed his results in 1930. The method was taken up in Boston by Dresser,⁴⁷ and case series begun both at the Pondville State Hospital and at the Collis P. Huntington Memorial Hospital. Grantley Taylor⁴⁸ has recently reviewed the experience and concluded that artificial menopause induced by radiation in patients with inoperable or recurrent carcinoma of the breast has a definite palliative effect in about one third. Bone metastases respond best. In a series of 47 cases of operable carcinoma of the breast in younger women, in whom artificial menopause was induced as a prophylactic measure, Taylor found no increase in the survival rate.

In the meanwhile a good deal of experimental evidence has accumulated showing the complexity of the relationships of hormones to carcinoma of the breast.⁴⁹ The administration of certain ovarian and testicular hormones for carcinoma of the breast has recently been tried extensively. Adair and Herrmann⁵⁰ reported highly favorable results with large doses of testosterone propionate. In interpreting these effects it must be kept in mind that the administration of large doses of androgen suppresses ovarian function in a manner somewhat comparable to castration by surgery or radiation. Estrogens were given therapeutically by a number of English physicians who, in 1944, reported striking palliation in occasional patients. Nathanson has recently described similar results, emphasizing that the favorable effects are limited to old women; in younger women the hormone stimulates carcinoma of the breast.

Enough time has not yet gone by to permit critical evaluation of the usefulness of this new hormonal therapy. Its indiscriminate use is doing a good deal of harm. The disadvantages of androgen therapy in women have not been stressed. Physicians should realize that doses of 100 mg. given intramuscularly twice a week, as have been recommended, will lower the pitch of the voice, produce a profuse growth of hair on the face, coarsen the skin and change the facial expression, and produce disturbing erotic symptoms. It is also worth mentioning that testosterone propionate is a very expensive product.

Although androgen treatment will relieve pain due to bone metastases in at least one third of the patients, and will make most of them feel better generally, in the great majority of cases it has little or no effect on the progress of the bone lesions themselves. In patients having maximal doses of androgen continuously for more than a year and who did not receive any radiation treatment for the bone metastases, we have watched the steady growth of the areas of bone destruction, although the patients were free of pain. We have not seen any benefit to visceral metastases from androgen treatment.

These facts have led us to prefer radiation to androgen treatment whenever the bone lesions are sufficiently localized to make radiation practicable. It is a surer method of temporarily checking the progress of the bone

lesions, and it has fewer unpleasant concomitant effects. We reserve the androgen treatment for patients in whom radiation has failed or in whom the bone metastases are generalized.

SUMMARY

Carcinoma of the breast remains the most important cancer problem, not only because it is by far the most frequent form of cancer, but because it is one of the most favorable types of the disease when promptly diagnosed and well treated. Radiation has failed to cure, although it remains an important means of palliation. When cases have been selected according to proper criteria of operability more than 50 per cent of five year cures can be obtained.

Efforts should be concentrated on educating women to detect their own tumors of the breast and to go promptly to a physician, and in educating physicians to use the knowledge we have available today in a way that will provide the best possible diagnosis and treatment.

Clinical Notes, Suggestions and New Instruments

AQUEOUS PENICILLIN THERAPY FOR PNEUMOCOCCIC PNEUMONIA

Injectations at Twelve Hour Intervals

ALISON HOWE PRICE, M.D.
Philadelphia

The custom of injecting aqueous solution of penicillin intramuscularly or intravenously, or of giving it orally, at short intervals of three or four hours is based on the fact that the amount of penicillin in the blood rises and falls rapidly after its administration. It is believed that closely spaced dosage is necessary to maintain a constant bacteriostatic or bactericidal amount of penicillin in the blood to control infection. To avoid the need for rapidly repeated injections, which cause discomfort, disturb sleep and burden the nursing service, methods of injecting penicillin in various slowly absorbed matrixes were developed with the view to providing a continuous slow release of penicillin into the blood and the maintenance of a constant large amount therein. Unfortunately, injections of this kind often cause pain, unpleasant reactions and at times sterile abscesses and are costly.

It is questionable whether the amount of penicillin in the blood is of more importance than the amount in the tissues and interstitial fluid in the control of pneumococcic pneumonia. The latter would seem to be more essential. Penicillin accumulates in large amount in the lungs of dogs.¹ The amount of penicillin in tissue is, of course, dependent on the amount carried to it by the blood, but it is reasonable to assume that the amount in the tissues rises more slowly and persists longer. The retention of penicillin in tissue or tissue fluids after a single injection is indicated by its excretion in the urine long after the amount in the blood has become so low that it can no longer be demonstrated.² Based on this reasoning, experimental therapy was conducted in patients with pneumococcic pneumonia by injecting penicillin in aqueous solution, intramuscularly or intravenously, in amount of 200,000 units as an initial dose and 100,000 units every twelve hours.

Between September 1945 and September 1947, 65 patients with lobar pneumonia (table 1) were treated with aqueous penicillin injected twice daily. Up to March 1946, of 36 patients, 16 were treated in the customary manner with 25,000 units every three or four hours, and 20 received the larger

injections twice a day. After this time all patients with pneumococci infections admitted to the ward service were treated twice daily, with an initial intravenous injection of 200,000 units of penicillin in aqueous solution and 100,000 or 200,000 units intramuscularly every twelve hours. The clinical response was as favorable in the 65 patients treated only twice daily as in patients treated at short intervals.

The temperature usually fell to normal after twenty hours of therapy; there were no relapses or focal localizations. However, 1 patient presented a large sterile pleural effusion. The mortality rate in these unselected patients, as compared with a group treated every four hours during the day but given no penicillin during the night,³ is shown in table 2.

CONCLUSION

Patients with pneumococci pneumonia who received injections twice daily with large doses of penicillin in aqueous solution responded as favorably to treatment as those receiving the same total dosage given at more frequent intervals. Injections at twelve hour intervals have the advantage of permitting undisturbed sleep, fewer needle pricks and a saving of nursing time. Aqueous solution of penicillin causes fewer unpleasant reactions, is less difficult to administer and is less expensive than penicillin specially prepared for slow absorption.

"The Royal Disease."—During the last ten years several scientists (Gunn, and Haldane, etc.) have tried to trace back to its origin the abnormal gene exhibited in the Russian and the Spanish royal families, and in several other princely families in Europe. As far as existing evidence is conclusive, Queen Victoria of England was the first carrier of the morbid gene. Ten of Victoria's male descendants have suffered from hemophilia and seven of her female descendants have been proved to be carriers of the gene. . . . The question arises from where and how Queen Victoria acquired the fateful gene of hemophilia. A definite answer to this question will be difficult if not impossible. . . . Haldane suggests an alternative possibility that the gene for hemophilia may have originated by mutation in Queen Victoria herself. Such instances of spontaneous mutation are well known in animals and plants, and Haldane is convinced that the hemophilia locus mutates rather frequently in human beings.—Hugo Iltis, Mendel Museum, Fredericksburg, Va., *The Journal of Heredity*, April 1948.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, Secretary.

ACOUSTICON HEARING AID, MODEL A-100, ACCEPTABLE

Manufacturer: Dictograph Products, Inc., 580 Fifth Avenue, New York 19.

The Acousticon Model A-100 is an "all-in-one" wearable hearing aid. The case contains microphone, amplifier and batteries. A radio pickup, provided as an accessory, plugs in along one side of the case. Without this attachment, the outside dimensions of the instrument are 122 by 64 by 22 mm. (4 13/16 by 2 1/2 by 7/8 inches) exclusive of the clothing clip. A wheel type on-off switch combined with gain control is at the top near one corner. The off position is marked, but has no snap to indicate off by touch. The four position slide tone control is located at one edge close to the same corner as the gain control. The receiver cord inserts at the top of the instrument.

Acousticon Model A-100

The lower half of the back opens to expose the battery compartment. The A battery is of the mercury type; the B battery is a 22.5 volt zinc-carbon type. The power consumption of the A battery, 1.3 volts, is 40 milliamperes, and the drain of the B battery, 22.5 volts at volume control three-fourths on, is 0.85 milli-ampere. With batteries, but without cord, receiver and radio attachment, the instrument weighs 213 Gm. (7 1/2 ounces); with the radio attachment it weighs 243 Gm. (8 1/2 ounces).

The following data were obtained in a performance test by an independent laboratory:

Subject	Acoustic Gain	Articulation Scores			Difference
		Acousticon Model A-100	Reference Instrument		
A	41 db.	77%	80%	—3%	
B	41 db.	45%	65%	—20%	
C	47 db.				

One of the other receivers of the Acousticon line might have given a better articulation score for this subject, but the complete line of receivers was not available for test. Furthermore, it was impractical to test this subject with all possible combinations of receivers, tone control settings and microphones. There are nine different receivers available.

The acoustic gain was found to meet the Council's published minimum requirements. Some of the volunteer subjects were especially interested in the radio attachment.

The Council on Physical Medicine voted to include the Acousticon Hearing Aid, Model A-100, in its list of accepted devices.

SUPER-FONIC HEARING AID ACCEPTABLE

Manufacturer: American Sound Products, Inc., 2454 S. Michigan Avenue, Chicago 16.

Super-Fonic Hearing Aid.

The Super-Fonic Hearing Aid is a plastic-cased, self contained hearing aid, with the battery compartment at the lower end of the case. A bottom-hinged full height back cover gives access to the batteries and another plastic case enclosing the amplifier. Either of two brush-crystal type receivers can be used, each with a plastic-covered cord for connections to the amplifier.

Two wheel type control knobs are placed at the top of the case. One is a volume regulator, and the other a four position tone selector, one position being "off." The design of the case for pocket size eliminates the need of a clothing clip.

The dimensions are 73 by 70 by 32 mm. (2¾ by 2¾ by 1¼ inches) and the weight is 170 Gm. (6 ounces). The A battery is of the mercury type, 1.3 volts, and the B battery of the zinc-carbon type, 30 volts. The A battery drain is 60 milliamperes and the B battery is 0.36 milliampere when quiet, 0.55 milliampere when the instrument is "squealing."

Acoustical Gain.—Measurements were made of the acoustical gain in decibels (sound pressure in 2 cc. coupler in decibels above sound pressure at microphone with microphone set in 40 by 40 cm. baffle) with the input level held at 0.02 dyne per sq. cm.

The following tabulations give the results in decibels for the large receiver, with volume control full on, for two settings of the tone control at each of seven different frequencies:

Frequency	256	512	1,024	2,048	2,250	3,100	4,096
Tone, 1 dot.....	38	49	64	49	51	50	47
Tone, 3 dots.....	30	41	56	33	35	29	25

For the small receiver, with the volume control full on, the following results in decibels were obtained:

Frequency	256	512	1,024	1,800	2,250	3,100	4,096
Tone, 1 dot.....	26	42	45	55	48	49	37

Below are approximate values of maximum sound pressure levels, at three frequencies, set up in the 2 cc. coupler with volume set for full gain and tone setting at one dot:

Frequency	Input Level	Maximum Output Level
600 cycles	60 db.	110 db.
1,024 cycles	65 db.	123 db.
2,048 cycles	60 db.	104 db.

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth giving about 30 decibels in sound reduction. The speaking person was outside the booth using a normal speaking voice. Score made under these conditions was 30 per cent.

The Council on Physical Medicine voted to include the Super-Fonic Hearing Aid in its list of accepted devices.

The acoustical gain for speech was measured with the help of two hard of hearing persons, each an experienced user of hearing aids. These subjects had about 60 decibels loss of hearing for speech, and the impairment was predominantly of the middle ear type, which obtains best results with hearing aids. Each was studied in a sound-proof room with a high quality sound amplification system (speech audiometer), and the performance with the hearing aid was compared with the performance without. The difference, the wide range tone control being used, was 50 decibels. (This amount of gain cannot be anticipated by persons with inner ear impairments).

The Council on Physical Medicine voted to include the Telex Model 97 Hearing Aid in its list of accepted devices.

AUREX HEARING AID, MODEL F, ACCEPTABLE

Manufacturer: Aurex Corporation, 1117 North Franklin Street, Chicago 10.

This is a plastic-cased, self-contained hearing aid, with the battery compartment at the lower half of the case. A snap cover gives access to the batteries. The crystal receiver has the Aurex trademark and is connected to the amplifier by a plastic covered cord (plugs at both ends).

One sliding type control on the side of the case serves as a switch and volume control. A rotary fan-type shutter may be turned from the center of the grill to close the microphone openings and serves as a partial tone control.

Aurex Model F Hearing Aid.

Dimensions and Weight

Dimensions: 130 by 60 by 22 mm. (5¼ by 2¾ by ¾ inch).
Weight: Approximately 198 Gm. (7 ounces).

	Voltage	Current
A 1½ volts	1.4 volts	40 milliamperes
B 22½ volts (Quiet)...	22 volts	0.4 milliampere
(Squealing)...	22 volts	0.5 milliampere

Acoustical Gain

Measurements were made of the acoustical gain of the instrument in decibels. This is the decibel difference in sound pressure between the pressure at the face of the microphone opening (with instrument set in 16 by 8 inch, 40.6 by 20.3 cm., baffle) and the sound pressure produced by the receiver in a 2 cc. coupler. The microphone sound pressure was held at a level of 40 decibels over 0.0002 dyne per square centimeter. Typical results, obtained with the volume control full on, for two settings of the tone control at each of seven different frequencies, are here tabulated:

Frequencies	256	512	1,024	1,200	2,250	3,100	4,096 cycles
Tone-Control							
Shutter open	50	58	61	69	57	52	40 db.
Shutter closed	45	55	56	62	42	43	33 db.

Maximum Output Pressure

Measurements were made of the approximate maximum sound pressure the instrument would produce in the 2 cc. coupler with the instrument set for full gain and with shutters open. Levels are in decibels relative to 0.0002 dyne per square centimeter.

Frequency	Input Level	Maximum Output Level
600 cycles	55 db.	110 db.
1,024 cycles	60 db.	117 db.
1,200 cycles	60 db.	120 db.
2,048 cycles	55 db.	102 db.

Intelligibility Tests

Intelligibility tests (random words) were made with a person of normal hearing seated inside a booth giving about a 30 decibel sound reduction. The speaking person was outside the booth

TELEX MODEL No. 97 HEARING AID ACCEPTABLE

Manufacturer: Telex, Inc., Telex Park, Minneapolis 1, Minnesota.

The Telex Model 97 is a three tube air-conduction hearing aid with the batteries contained in the amplifier case. The case is constructed of flesh-colored plastic material. A side-hinged full length back cover gives access to the battery compartments and tubes. The magnetic type receiver is connected to the top of the amplifier case by means of a light plastic-covered cord which has dual pin plugs at each end.

A single wheel type control is at the top of the case and is set at right angles to the long axis of the case. This control is a combination of "on-off" switch and volume control. Alongside this control is a two position tone control lever or switch; position 1 gives wide range response and position 2 gives attenuated low frequency response. An attachment clip is fastened to the back of the amplifier case.

With batteries, the instrument weighed 174 Gm. (6¼ ounces); it measured 111 by 59 by 23 mm. (4¾ by 2¼ by 2⅜ inches). For the A battery it requires a 1.3 volt mercury type of cell; the B battery, of the zinc-carbon type, is 22½ volts. The power consumption was measured in an independent laboratory and was found to be 48 milliamperes for the A battery at 1.25 volts and 0.36 milliampere for the B battery at 21 volts.

Acoustical gains were also measured at six frequencies and two positions of the tone control, with the volume control set for maximum gain. The results are here tabulated:

	Frequencies					
Tone Control	250	500	1,000	2,000	3,000	4,000 cycles
Position 1.....	48	52	56	52	51	25 db.
Position 2.....	35	43	61	50	61	25 db.

using a normal tone of voice. The score made under these critical conditions was 62 per cent.

The Council on Physical Medicine voted to include the Aurex Hearing Aid, Model F, in its list of accepted devices.

NATIONAL HEARING AIDS STANDARD MODEL (T), STAR MODEL (S) AND CUB MODEL (C) ACCEPTABLE

Manufacturer: National Hearing Aid Laboratories, 815 South Hill Street, Los Angeles 14.

These three hearing aids are all self-contained metal-cased instruments with a battery compartment in the lower half of the case. The crystal receiver connects by a 2-conductor cord with plugs at both ends. There are two wheel-type controls on top of the case. One is the volume control; the other is a combination switch and tone control. Wearing clips on the front of the case are placed to keep the microphone opening above the edge of the pocket.

Specimens of the Standard, Star, and Cub models were investigated in a laboratory acceptable to the Council.

STANDARD MODEL HEARING AID (T)

The Standard model is the largest made by the firm. The battery compartment in the lower half of the case has a hinged cover for access.

The dimensions are 125 by 33 by 65 mm. (5 by 1¼ by 2½ inches) and the weight is 237 Gm. (8½ ounces). The A battery is of the zinc-carbon type, 1½ volts, and the B battery of the zinc-carbon type, 22½ volts. The A battery drain is 40 milliamperes and the B battery is 0.4 milliamperes when quiet and 0.2 milliamperes when the instrument is "squealing."

Acoustical Gain.—Measurements were made of the acoustical gain in decibels. This is the decibel difference between the sound pressure at the face of the microphone of the instrument and the pressure produced by the receiver in the 2 cc. coupler. The pressure at the face of the microphone was held at approximately 55 decibels above zero for these measurements (55 decibels above 0.0002 dyne per square centimeters).

Typical acoustical gains in decibels are given in the following tabulation:

Volume	Tone	Frequencies						
		256	512	1,024	1,200	2,250	3,100	4,096
Full	1-dot	27	38	54	57	42	42	28
Full	2-dots	23	32	48	48	27	23	12

Maximum Output Pressure.—Below are approximate values of maximum sound pressure levels (at four frequencies) set up in the 2 cc. coupler with the volume set for full gain and tone setting 1 dot.

Frequency	Input Level	Maximum Output Level
600 cycles	75 db.	120 db.
1,024 cycles	85 db.	130 db.
1,200 cycles	85 db.	131 db.
2,048 cycles	85 db.	117 db.

Intelligibility Tests.—Intelligibility tests were made with a person of normal hearing seated inside a booth giving a sound reduction of about 30 decibels. The speaking person was outside the booth using normal speaking voice. Score made with the Harvard No. 9 lists under these critical conditions was 73 per cent.

STAR MODEL HEARING AID (S)

This instrument, tube combination 11 A, is represented by Model S. The battery compartment in the lower half of the case is covered by a leather band for access.

The dimensions are 120 by 33 by 65 mm. (4¾ by 1¼ by 2½ inches) and the weight is 265 Gm. (9½ ounces). The A battery is of the zinc-carbon type, 1½ volts, and the B battery

of the zinc-carbon type, 22½ volts. The A battery drain is 40 milliamperes and the B battery is 0.6 milliamperes when quiet and 0.4 milliamperes when the instrument is "squealing."

Acoustical Gain.—Measurements were made of the acoustical gain in decibels by the technique described for A.

Typical acoustical gains in decibels are given in the following tabulation:

Volume	Tone	Frequencies						
		256	512	1,024	1,200	2,250	3,100	4,096
Full	1-dot	31	36	59	62	50	38	36
Full	3-dots	25	31	51	48	29	17	15

Maximum Output Pressure.—Below are approximate values of maximum sound pressure levels (at four frequencies) set up in the 2 cc. coupler with the volume set for full gain and tone setting 1 dot.

Frequency	Input Level	Maximum Output Level
600 cycles	80 db.	124 db.
1,024 cycles	75 db.	132 db.
1,200 cycles	75 db.	131 db.
2,048 cycles	85 db.	120 db.

Intelligibility Tests.—Intelligibility tests were made with a person of normal hearing seated inside a booth giving a sound reduction of about 30 decibels. The speaking person was outside the booth using normal speaking voice. Score made with the Harvard No. 9 lists under these critical conditions was 73 per cent.

CUB MODEL HEARING AID (C)

The Cub Model is the smallest of the three hearing aids submitted by the firm. The battery compartment in the lower half of the case has a hinged cover for access.

The dimensions are 102 by 33 by 65 mm. (4 by 1¼ by 2½ inches) and the weight is 190 Gm. (6¾ ounces). The A battery is of the zinc-carbon type, 1½ volts, and the B battery of the zinc-carbon type, 22½ volts. The A battery drain is 40 milliamperes and the B battery is 0.5 milliamperes when quiet and 0.3 milliamperes when the instrument is "squealing."

Acoustical Gain.—Measurements were made of the acoustical gain in decibels by the technique described for A.

Typical acoustical gains in decibels are given in the following tabulation:

Volume	Tone	Frequencies						
		256	512	1,024	1,200	2,250	3,100	4,096
Full	1-dot	31	44	53	53	33	33	28
Full	3-dots	25	34	46	45	22	17	13

Maximum Output Pressure.—The following are approximate values of maximum sound pressure levels (at four frequencies) set up in the 2 cc. coupler with the volume set for full gain and tone setting 1 dot.

Frequency	Input Level	Maximum Output Level
600 cycles	75 db.	121 db.
1,024 cycles	85 db.	131 db.
1,200 cycles	85 db.	131 db.
2,048 cycles	85 db.	115 db.

Intelligibility Tests.—Intelligibility tests were made with a person of normal hearing seated inside a booth giving sound reduction of about 30 decibels. The speaking person was outside the booth using normal speaking voice. Score made with the Harvard No. 9 lists under these critical conditions was 55 per cent.

The National Hearing Aid Laboratories provide for use by salesmen a device called the Selector-Tester. When the hearing aid is fitted this equipment may be used, although a trial of a week is considered by the Council as a more accurate method of selecting a satisfactory hearing aid.

The Council on Physical Medicine voted to include National Hearing Aids Standard Model (T), Star Model (S) and the Cub Model (C) in its list of accepted devices.

SATURDAY, SEPTEMBER 25, 1948

DOCTORS FOR THE ARMY

The medical departments of our armed forces, and particularly the Army, confront a crisis. The new Selective Service Act has established a peacetime army and air force at approximately five times the size of the prewar military establishment. Estimates indicate that they must have 4,000 more doctors by June 1949. However, possible economies may diminish this need slightly. None of the physicians needed is obligated by any existing law to volunteer or to serve in the armed forces. The special need of the armed forces, as pointed out by Surgeon General R. W. Bliss in this issue of *THE JOURNAL*, is its requirement for specialists. Today in many of our leading Army hospitals abroad young men who have hardly had an adequate residency are in full charge of medical, surgical, obstetrical and other highly specialized departments.

The House of Delegates of the American Medical Association established the Council on National Emergency Medical Service as a body to be especially concerned with meeting the needs of the nation for physicians in times of emergency. War today is total war. The needs of civilian populations and particularly of great industries, which are the backbone of war, must also be considered. Nevertheless, the men who do the actual fighting, who fly the planes, who get the foods and supplies up to the front and who carry the banner of the United States all over the world must have the highest possible quality of medical service in order to keep fit and efficient. The provision of the best medical care to our armed forces is one of the most economical steps that the nation can undertake. It lessens the total demand for men, and it maintains the morale and the spirit of the men more than any other single factor involved in modern war.

The Council on National Emergency Medical Service, the procurement divisions of our armed forces, the headquarters of the Army and Navy and Air Force have all been desperately concerned during the last few months with meeting the nation's need. Every

possible approach to the problem has been considered. Now that compulsory service for physicians has been denied by the Congress, the needs must be met by other technics. Obviously the first step is to make the service more and more attractive to the young men so as to encourage volunteering by greater and greater numbers. A recent somewhat casual survey of the young men now in the service who will be leaving at the end of two years of service indicates that the following factors must be given consideration in attracting them for longer periods:

1. The service must be sufficiently varied so that the deadly routine of day by day dispensary service of many months does not destroy the young man's initiative.

2. At least one half of the young men now in the armed forces want ultimately to qualify for certification by some specialty board. Some means must be found whereby service in military installations can be reckoned as a part of the young man's development leading toward certification.

3. Except in the most remote areas young men may be kept in contact with some of the best teachers in American medicine. Already a steady stream of qualified consultants is visiting our Army hospitals throughout the world, and the men who are taking charge of the services in these hospitals are having more opportunity for extended contact with the leaders in the various medical specialties than most of the men who remain in the United States. All that appears to be needed is some arrangement for the development of a systematic course of instruction rather than casual ward walks.

Thus most of the objections can be met by competent planning. While the young men prefer to be rotated from one service to another at fairly frequent intervals, several difficulties have developed in this regard. First is the housing of young men, many of whom are married and are already en route to the development of families. One colonel in charge of a hospital of many hundreds of beds in Germany said that there would be no problem for the Army medical department if all the young doctors would remain bachelors until they had completed their military service. The housing of young physicians and their families, as can easily be seen, is one of the most difficult of the problems that confront the armed forces.

It has been suggested that increased pay in the armed forces for men as highly specialized as are physicians and engineers would attract more young men to the service. Actual first hand surveys indicate, however, that the money, while interesting, is not a primary consideration.

A specific provision in the Selective Service Act states that a man may not be inducted into the armed

forces until provision has been made for adequate medical care. That was the intent of the Congress. There is no reason to believe that the Congress will withdraw from that intent. There is actually reason to believe that the Congress will make that intent fully effective by some type of compulsory selection of young physicians unless these young men come forward to fulfil their obligation as citizens and particularly as physicians. They are not being asked to do any more than is being asked of any other person in our population.

The world is trembling on the edge of a great third war. Many of our leaders in history and economics are convinced that such a war might well mean the end of civilization as we now know it. One needs only to see the dreadful devastation that prevails in London, Belgium, Rotterdam, Frankfurt and Berlin to realize that every American must be ready to give of his utmost now that the call is here and thus to keep away such horrible destruction from our own shores. Only those who have actually seen at first hand whole square miles of devastation in London, Berlin, Rotterdam and other great capitals of the world can comprehend the threat. The profession of medicine places on the young men who choose it as a career a great responsibility. They are not asked to venture their lives in war to the same extent as are other young men in the population. They are asked instead to put other young men into the best possible condition to meet the need and to salvage the human wreckage so far as possible when war actually begins. The medical profession of the United States has a record enviable beyond that of any other medical profession in the world for what it has accomplished when the nation called. Let us realize that now we can no longer wait until the enemy is at the gate. The time to prepare is in advance of the struggle, and the call has come.

MR. EWING'S TEN YEAR HEALTH PROGRAM

The National Health Assembly apparently has culminated in a book called "The Nation's Health: A Ten-Year Program," obtainable for \$1 from the Superintendent of Documents in Washington. As any one with knowledge of the background could have predicted, the report is devoted largely to arguments in support of a government health insurance program, principally emphasis on the alleged parlous state of the health of the American people. The answers to the nation's health problem developed by the Ewing report include, first, more doctors, dentists, nurses and other auxiliary med-

ical personnel; second, the addition of 600,000 hospital beds by 1960, and, third, a nationwide compulsory sickness insurance plan. Here are the same old figures that the proponents of government medicine have been launching at periodic intervals for the last twenty or thirty years. Some of them are requoted in a Washington Letter in this issue of *THE JOURNAL*. These undocumented statistics would be ignored if they were not being used in such a desperate, final gasp by the Federal Security Agency.

In an interview to the press on September 2, President Truman supported the Ewing program, saying that he is compelled to advocate national health insurance because he sees no other possible way of bringing medical service to fully half the American people. Just how hard has the administration tried to see some other way? Just whom have they called upon to help them look?

Recently the general assembly of the World Medical Association met in Geneva with a considerable number of nations of the world represented. Reports were received on conditions related to medical care in more than twenty nations. The amount and quality of medical care given to most people of the world under their compulsory sickness insurance plans would never satisfy the people of the United States. The inevitable faults of these systems, which have been emphasized to the American physicians and to the American people for a good many years, are now coming vividly to light. Great Britain embarked on its new National Health Act on July 5. People in England may now go to the doctor without calculating the cost of the service. They may be supplied with spectacles and teeth without additional costs. They may have consultants and beds in hospitals without reference to individual payments for services rendered. That is what the National Health Act of Great Britain promised them. Do you think that they get it? No, indeed! They queue up to see the doctors whom formerly they could have seen by appointment. Doctors are compelled to write formulas and prescriptions and reports many hours in advance of the time when they see the patients because otherwise they would never have time to see the patients. Many a physician is already satisfied that he cannot work under the Act. The unfortunate public have no way of knowing whether or not what they get is good medical service or something to make them think that they are being given attention. The greatest folly in the world is the manner in which Great Britain embarked on a nationwide health service without hospitals, doctors, nurses, drugs or money to supply what they promised, and an even greater folly would be the attempt to offer a similar service in the United States and to gulp the

entire medical problem of the nation in a single swallow. Should the United States accept the prescription by President Truman and his consultant, Mr. Ewing, it would likely discover that the prescription had little of curative value and a great deal of the ultimate effect of ipecac or apomorphine (these, Mr. Ewing, are classified by the books on drugs as emetics).

Current Comment

TIME FOR DECISION

Many issues confront the voters of the United States in the election that will occur in November. Most Americans so value their democratic prerogatives that they sincerely attempt by their ballots to influence the policies of their government. As is explained in an editorial in this issue of *THE JOURNAL*, President Truman is committed to a nationwide system of compulsory sickness insurance. Governor Thomas E. Dewey has stated over his signature and in a public address to the Oregon State Medical Society that he is unalterably opposed to a government system of medical practice. In the United States legislation is the ultimate responsibility of the Congress. Those who feel strongly in behalf of certain policies or opposed to them must be equally concerned, therefore, not only with the election of a president but also with the election of senators and congressmen who will support the president. Regardless of what the proponents of compulsory sickness insurance may say, the health of the nation is not in a critical condition. In fact, the people of the United States are more healthy than those of any other country of the world. The quality of medical service available to the vast majority is superior to that anywhere else in the world.

SEX LIFE IN PRISON

Karpman¹ calls attention to the prevalence of abnormal sex practices in prisons. The more normally constituted prisoner with a short sentence may succeed, at least temporarily, in maintaining his heterosexuality. Sooner or later, self control breaks down and the prisoner is confronted with the choice of some abnormal sexual practice. The ease with which one succumbs to the practice of masturbation varies greatly, some going through an acute emotional conflict before they finally yield and some, who are never able to succumb, developing neurotic or psychotic reactions. Karpman believes that much of the prison rioting may be traceable to sex problems. If the practice of masturbation and homosexuality continues, it becomes fixed, and even on discharge from confinement a person often finds himself unable to return to normal sex activities. Young men, of whose heterosexuality there was no previous doubt, after confinement for several years become con-

firmed homosexuals, taking on feminine characteristics on discharge and becoming homosexual prostitutes with consequent demoralization of younger elements whom they initiate. Prison authorities thus far have used only violent suppression to control sex, and the method does not seem to have the intended effect. The various suppressions engender hatred and defiance which still further stabilize the reaction. Karpman believes that abnormal sexual practices in prisons have probably not decreased. A person who has served even a brief sentence and has yielded to abnormal sex practices can be considered on discharge from prison as abnormal; if before confinement he was heterosexual, his term in prison incapacitates him for normal sex adjustment. As a remedial measure within the prison, Karpman believes that provision for more normal sex outlets would help correct these practices. He expresses the hope that when hospitals take the place of prisons, the abnormal sex practices of prisoners will disappear.

OUTBREAKS OF DISEASE FROM CONTAMINATED FOOD

The United States Public Health Service has just released a compilation of disease outbreaks in 1946 conveyed through foods other than milk and milk products. The 299 outbreaks of disease from contaminated food incapacitated 12,526 persons, 17 of whom died. The food was usually contaminated through unsanitary conditions or infection of food handlers; also early and adequate refrigeration was lacking. From 1938 through 1946, outbreaks traced to foods have been nearly six times as numerous as those traced to water or milk. During the war years, food-borne diseases increased, while disease outbreaks attributed to water and milk declined. The economic loss from milk-borne diseases alone has been estimated as at least \$3,000,000 a year. Sanitary standards for eating and drinking establishments developed by the Public Health Service have been adopted in local areas throughout the country containing over 60,000,000 persons. These standards are now in effect statewide in 17 states and the District of Columbia and in 186 counties and 451 municipalities in 40 states and territories. To help states and local communities organize classes for employees in food establishments, a pamphlet, "Guide to Safe Food Service," may be obtained by addressing the Sanitary Engineering Division, Public Health Service, 4218 Federal Security Building South, Washington, D. C.

INDEX NUMBER

In this issue of *THE JOURNAL* appears the Index for Volume 137 of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* covering May, June, July and August. This Index should have appeared in *THE JOURNAL* of August 28, but it was impossible to publish it at that time. The Index is paged to follow immediately the material that ended Volume 137 and may be bound with that volume so as to make it complete.

ORGANIZATION SECTION

1868

Will C. Braun

1948

Great organizations and great institutions reflect the lives and earnestness of great men. When the ultimate history of the growth of the American Medical Association is written, among the names that will loom largest along with those of Drs. Nathan Smith Davis and George Henry Simmons, editor and general manager of the Association, will be that of Mr. Will C. Braun, first business and circulation manager.

Will Braun died Sunday, Sept. 12, 1948, at the age of 80 years. He had devoted 56 of those 80 years to the work of the American Medical Association, and he brought to that work a canny mind and a whole-hearted sincerity. Will Braun was born in Ripley, Ohio, on Aug. 24, 1868. In November 1891 Mr. Braun, who had been clerking in a general store in Ripley, Ohio, came to Chicago in search of greater opportunity. The American Medical Association offered him a job as subscription solicitor and all-around office helper. At that time Dr. J. C. Culbertson was editor and manager of *THE JOURNAL*. The headquarters space was a room about 30 by 60 feet, occupied by a staff of two men, two women, some typesetters and a proofreader. The office was marked off from the rest of the area by a wood railing. In 1892, at just about the time he had worked up a good revenue by selling subscriptions and advertising space on a commission basis, *THE JOURNAL* got a new editor, Dr. John B. Hamilton. Will Braun thought that this would terminate his employment, but Dr. Hamilton put him on a regular salary, and the business began to expand.

Mr. Braun was continually in process of urging Dr. George H. Simmons to greater development and expansion of the headquarters office.

From 1902 to 1942 there were seven remodelings and rebuildings. These were associated with a continuous growth in the circulation of *THE JOURNAL*, from 3,500 in 1891 to more than 100,000 in 1941 and to a total today, at the time of Will Braun's death, of more than 140,000 copies weekly. The handful of employees has increased to more than 800. Much of this tremendous development is a direct result of the genius of Will Braun in advertising. In the

course of his work he made numerous friends among the great leaders of the American industries allied to medicine. Some of the original contracts which he developed have been continued without intermission since that time. In 1946 he became Business Manager Emeritus and was succeeded by Mr. Thomas R. Gardiner, who had been associated with him as first assistant for many years. At that time his friends and associates tendered him a magnificent banquet at the meeting in San Francisco.

The impetus given to the growth of the American Medical Association by Dr. Nathan

Smith Davis, Dr. George H. Simmons and Will C. Braun was so powerful that it remained for their successors simply to hold the forward surge firmly to the goal. The quality of the many publications of the Association, their uniformly high standards of advertising and their conspicuous success, are an indication of the type of support given by the business administration to the Board of Trustees and the editors. That policy was recognized by Will Braun as fundamental toward continued progress in medical publications, and it made him proud and happy at the time of his death to see the ideals and the effort behind them bear such abundant fruit.

Official Notes

DR. HAROLD R. HENNESSY APPOINTED SECRETARY TO COUNCIL ON NATIONAL EMERGENCY MEDICAL SERVICE

Dr. Harold R. Hennessy, Winnetka, Ill., formerly a resident of California and since early 1946 associated with the Council on Industrial Health, has recently been appointed Secretary to the Council on National Emergency Medical Service. Dr. James C. Sargent, Milwaukee, is Chairman of the Council, which was formed in 1947 to coordinate efforts of the American Medical Association involved in the mobilization of our nation's armed forces, industry, agriculture and civilian population in time of a national emergency.

Dr. Hennessy, a graduate of the University of Minnesota Medical School in 1930, practiced for a number of years in Southern California. A medical reserve officer for many years, Dr. Hennessy now holds the rank of colonel. During the war he was assigned to the office of the Surgeon, Ninth Service Command, later attending the School of Military Government, University of Virginia, Charlottesville. Overseas for two years, he was assigned to the G-5 Staff of the Communication Zone and later to the Fifteenth United States Army, where he served in the office of the Surgeon.

Washington Letter

(From a Special Correspondent)

Sept. 15, 1948.

Truman Indorses Ewing's 10 Year Health Program

At his first September press conference, whose date (September 2) coincided with White House release of Federal Security Administrator Oscar R. Ewing's ten year health plan for the nation, President Truman discussed and gave hearty indorsement to the report. It is in the form of a 186 page book, which the Federal Security Agency has begun distributing among state and local public health departments, state medical and dental societies, delegates to the National Health Assembly held here last May, voluntary associations in the health and medical field and certain other agencies. As a public document, the paper-bound book is for sale by Superintendent of Documents, Government Printing Office, Washington 25, D. C. The price is \$1. Its title is "The Nation's Health: A Ten-Year Program."

Nearly one third of the report is devoted to argument in support of government health insurance and exposition of alleged inadequacies of voluntary medical care and hospitalization plans. However, institution of compulsory insurance by the federal government is placed third on Mr. Ewing's priority list. His first goal is to increase medical manpower—physicians, dentists, nurses and their auxiliaries; his second, expansion of the country's hospital system so that at least 600,000 beds are added by 1960.

Other goals, in their order of mention: increased emphasis on mental health; reduction of the toll taken by chronic and degenerative diseases; complete rehabilitation of the physically handicapped; improvement of maternal and child health services; joint planning by professional and citizens' groups at community level to raise public health standards and, finally, establishment of more local public health departments with full time staffs.

Following are some of the statements made in the Ewing report:

"By and large, only the well-to-do and, to a certain extent, charity patients get satisfactory medical care. The in-between groups—other than the fairly small portion who are covered by voluntary insurance plans—are the ones desperately in need of better care."

"Every year 325,000 people die whom we have the knowledge and the skills to save."

"We have only 80 per cent as many physicians as we need and even greater shortages of other medical personnel."

"We have only about 50 per cent as many acceptable hospital beds as we require."

"A scant 20 per cent of our people are able to afford all the medical care they need."

"Only about half the families in the United States can afford even a moderately comprehensive health insurance plan, on a voluntary basis. The net result, then, would be to leave without adequate protection the very groups—those with incomes below \$3,000—whose plight the Nation needs most to remedy in order to raise the country's level of health."

"The compelling argument . . . that drives me to an advocacy of national health insurance is that I see no other possible way of bringing adequate medical service to fully half of the American people. It would, obviously, be nice if we could find some other way that would arouse less opposition from many members of the medical profession. But I see none."

Congressman Lauds World Health Assembly

Skeptical at the outset but now a supporter of the World Health Organization, Representative Ivor D. Fenton expressed his views in a statement in the *Congressional Record* for August 17 (page A5414). The Pennsylvania Republican, who is a physician, attended the first World Health Organization meeting in Geneva as a Congressional advisor to the United States delegation.

"When I accepted appointment to the U. S. delegation I was somewhat skeptical," said Dr. Fenton. "Now I can only give my strongest assurance that in the World Health Organization we have an unusual, perhaps a unique, opportunity to promote the general welfare of mankind and to improve the world economy, as well as increase our own protection against importation of disease."

Navy Forms Council on Radiobiologic Research

A Council on Radiobiologic Research within the Bureau of Medicine and Surgery, Navy Department, has been established by Rear Admiral Swanson, the Surgeon General. Among its responsibilities will be to review all proposed research project in radiation biology, diagnosis and therapy of radiation sickness internal radiation hazards and methods of photographic dosimetry and personnel decontamination. Serving on the Council whose first meeting is tentatively scheduled for October 12, will be representatives of the Office of Naval Research, the Armed Forces Special Weapons Project and the Atomic Energy Commission, as well as heads of divisions in the Bureau of Medicine and Surgery dealing with atomic defense and research.

Priority Buying of War Surplus by Hospitals Ended

As of September 1, priority and preference buying of war surplus supplies, equipment and miscellaneous materials by non-profit hospitals and educational institutions came to an end. Under the program conducted by the War Assets Administration, "millions of dollars worth of war surplus hospital equipment, including beds, surgical and medical equipment, drugs, medicines, dressings and furnishings went to public health institutions throughout the nation," said Jess Larson, War Assets Administration head. He added that donation of surplus property to eligible health and educational institutions will be continued, explaining that this is a disposal method rather than a priority.

Dr. J. T. Edsall Elected to Chemical Society Post

Dr. John T. Edsall, associate professor of biochemistry at Harvard Medical School, was elected chairman of the American Chemical Society's Division of Biological Chemistry at the annual meeting of the society in Washington which ended September 3. Jules D. Porsche, of Armour and Company, was elected vice chairman. Elected secretary to succeed Dr. Edsall was Dr. Paul W. Preisler, assistant professor of biochemistry at Washington University School of Medicine.

Marine Hospital Heads Will Meet September 24-27

Administrators of the twenty-four marine hospitals operated by the U. S. Public Health Service, together with heads of the service's four largest outpatient clinics, will hold their annual conference here September 24-27 at the call of Dr. Otis L. Anderson, head of the Public Health Service Hospital Division. Problems encountered during the past year will be reviewed and measures for improvement of services discussed. At present the twenty-four hospitals' combined patient load is about 6,000.

GOVERNMENT SERVICES

NAVY

NAVY INTERNS IN CIVILIAN INSTITUTIONS

The first group of young medical officers in the reserve corps have reported to the approved hospitals indicated below for active duty as interns under the new medical training program. These officers, all lieutenants (jg), are graduates of class A medical schools and, on completion of their internship, will remain on active duty in the Navy for at least one year.

McAlpin H. Arnold, Elberton, Ga., to Union Memorial Hospital, Baltimore.

William H. Brown, Newburgh, N. J., to City Hospital, Welfare Island, N. Y.

James A. Christensen, Seattle, to Providence Hospital, Seattle.

Roy Daugherty, San Antonio, Texas, to General Hospital, Kansas City, Mo.

Robert Edwards, Lawrence, Kan., to the Kansas Medical Center, Kansas City, Kan.

John W. E. Fries, St. Louis, to St. Louis County Hospital, Clayton, Mo.

George R. Hanson, Nampa, Idaho, to St. Luke's Hospital, Denver.

Ignatius P. Hanzly, Lackawanna, N. Y., to Mercy Hospital, Buffalo.

Harry E. Howard, Monroe, Mich., to Indianapolis General Hospital, Indianapolis.

Andrew G. Hudacek, Plymouth, Pa., to Reading Hospital, Reading, Pa.

John W. Jaes, Coats, Kan., to Indianapolis General Hospital, Indianapolis.

John M. Kenelly Jr., Hillsboro, Ore., to Clallinger Municipal Hospital, Washington, D. C.

Charles E. Kerrick, Parma, Idaho, to Creighton Memorial St. Joseph's Hospital, Omaha.

Ralph A. Kilby, Buffalo, to Hospital of St. Barnabas for Women and Children, Newark, N. J.

Frank A. Kopecky Jr., Omaha, to Creighton Memorial St. Joseph's Hospital, Omaha.

Stephen C. Leograndes, Framingham, Mass., to Cooper Hospital, Camden, N. J.

Robert E. Lewis, Oakmont, Pa., to University of Pittsburgh Medical Center Hospitals, Pittsburgh.

Harry C. Lockard Jr., Bedford, Va., to Charity Hospital of Louisiana, New Orleans.

Leo B. McGinty, Huron, S. D., to Creighton Memorial St. Joseph's Hospital, Omaha.

Donald J. Madden, Los Angeles, to Creighton Memorial St. Joseph's Hospital, Omaha.

Dean M. Miller, Abilene, Kan., to Kansas City General Hospital, Kansas City, Mo.

Harlan L. Papenuss, Winona, Minn., to Creighton Memorial St. Joseph's Hospital, Omaha.

Dwaine J. Peetz, Sidney, Neb., to Creighton Memorial St. Joseph's Hospital, Omaha.

Louis H. Porter, II, Austin, Texas, to Kansas City General Hospital, Kansas City, Mo.

Louis J. Prendergast, Fonda, Iowa, to Creighton Memorial St. Joseph's Hospital, Omaha.

Fred W. Richardson, Laconia, N. H., to Beverly Hospital, Beverly, Mass.

Hubert A. Ritter, St. Charles, Mo., to St. Mary's Group of Hospitals of St. Louis University, St. Louis.

Eugene J. Schmitt, Rochester, N. Y., to St. Mary's Hospital, Rochester, N. Y.

Clarence T. Thompson, Baton Rouge, La., to Charity Hospital of Louisiana, New Orleans.

James W. Vildibill Jr., Columbia, S. C., to Charity Hospital of Louisiana, New Orleans.

RESERVE OFFICERS RECALLED

The following reserve medical officers have been recalled to active duty: Capt. Stephen M. Smith of Danbury, Conn., to the Naval Hospital, Bethesda, Md.; Comdr. Sydney L. Williams, Flushing, N. Y., to the New York Naval Shipyard, Brooklyn; Lieut. Comdr. Charles N. Scott, Smithfield, W. Va., to the Naval Air Station, Willow Grove, Pa., as Station Keeper; Lieut. (jg) Harold W. Garvin, Mascoutah, Ill., to a residency in obstetrics and gynecology at the Naval Hospital, Great Lakes, Ill.

DR. ALVAREZ OPENS SERIES OF GUEST LECTURES

The first of the current series of guest lectures sponsored by the National Naval Medical Center, Bethesda, Md., was opened September 24 when Dr. Walter C. Alvarez spoke on "Puzzling Functional Disorders." The meetings are open to members of local medical societies and faculties, medical students and Army, Navy and Public Health and Veterans Administration medical officers.

AWARDS AND COMMENDATIONS

Lieutenant Frederick E. Wetzel

Lieut. Frederick E. Wetzel, M. C., has been authorized by the Navy Department to wear the Presidential Unit Citation ribbon with star by virtue of his service in the First Marine Division, which division was awarded the Presidential Unit Citation by the President of the United States. This citation of the division was as follows:

For extraordinary heroism in action against enemy Japanese forces at Peleliu and Ngesebus from September 15 to 29, 1944. Landing over a treacherous coral reef against hostile mortar and artillery fire, the First Marine Division, Reinforced, seized a narrow, heavily mined beachhead and advanced foot by foot in the face of relentless enfilade fire through rain, forests, and mangrove swamps toward the air strip, the key to the enemy defenses of the Southern Palau. Opposed all by thoroughly disciplined, veteran Japanese troops heavily entrenched in caves and in reinforced concrete pillboxes which honeycombed the high ground throughout the island, the officers and men of the division fought with undiminished spirit and courage despite heavy losses, exhausting heat and difficult terrain, seizing and holding a highly strategic air and land base for future operations in the Western Pacific. By their individual acts of heroism, their aggressiveness and their fortitude, the men of the First Marine Division, Reinforced, upheld the highest traditions of the United States Naval Service.

AIR FORCE

COURSES IN AVIATION MEDICINE

The Air Surgeon announces a thirty-seven week course to begin September 20 at Randolph Air Force Base, San Antonio, Texas, and open to civilian physicians who apply and are accepted for integration in the Regular Army and duty with the Air Force, to medical reserve officers on active duty who have applied for integration in the Regular Army, and to Regular Army medical officers. The course will provide instruction in care of the flyer, internal medicine, ophthalmology, naso-

pharyngeal radium irradiation, biophysics, physiology, pathology, surgery and other subjects.

In addition a six-week aviation medical examiner's course will begin November 1 at this air base, open to civilian physicians who are members of the Air National Guard and the Air Force Reserve. Completion of this course and duty with the National Guard or reserve units will make physicians eligible for designation as flight surgeons. Application for admission to either of the courses should be made to The Chief of Staff, United States Air Force, Office of The Air Surgeon, Washington 25, D. C.

VETERANS ADMINISTRATION

NEW HOSPITAL AT OMAHA

Ground was broken June 24 for the new 500 bed Veterans Hospital to be erected on the Field Club site in Omaha. The projected cost, including administrative and contract expendi-

New Veterans Hospital at Omaha.

tures, will be about \$11,321,800. The possible completion date is March 1, 1950. The project is under the supervision of the Omaha District Engineer Office of the Army Corps of Engineers.

DIRECTOR OF HOSPITALIZATION APPOINTED

The Veterans Administration announces the appointment of Dr. E. B. Quarles, formerly associate director at Barnes Hospital, St. Louis, as director of the Veterans Administration Hospitalization and Requirements Service. He is a graduate of the Medical College of Virginia, interned at Nassau Hospital, Mineola, N. Y., and at the Essex County isolation hospital, Belleville, N. J., and then engaged in industrial and general medical practice at America, Ala. He served with the Medical Corps of the Army during World War II.

OLD GUARDHOUSE BECOMES MEDICAL LABORATORY

The old guardhouse at Fort Logan, Colo., dating back to the founding of the fort in 1887, has been transformed into a modern medical research laboratory of the Veterans Administration and will be available to physicians and scientists of the Rocky Mountain Region. At the dedication of the laboratory recently among the speakers were Dr. J. E. Wallin, chairman, Rocky Mountain Section, Society for Experimental Biology and Medicine; Dr. Ward Darley, dean, University of Colorado Medical School; Dr. Cyril H. Francis, regional Veterans Administration medical director, and Dr. Martin G. Goldner, research director, Fort Logan Hospital.

PERSONALS

Dr. Edward E. Johnston has resigned as manager of the Nichols Hospital at Louisville and will enter private practice at Elizabethtown, Ky. Dr. Leverett S. Woodworth has been appointed assistant to the clinical director at the Nichols Hospital. Dr. Woodworth was formerly superintendent of the Massachusetts Memorial Hospital, Boston.

Dr. Howell Brewer, manager of the rehabilitation hospital at Fort Thomas, has been transferred to the veterans' branch office at St. Louis. Dr. Brewer will direct the physical medicine program in the ten hospitals under supervision of the regional branch office.

Dr. George J. Hathaway has resigned from the Veterans Administration to accept a position with the Wisconsin national veterans home at King, Wis.

Dr. Paul B. Magnuson, Chief Medical Director of the Veterans Administration, will attend the Ninth International Congress on Industrial Medicine in London and the Fourth Congress of the International Society of Orthopedic Surgery and Trauma in Amsterdam in September. Dr. Magnuson will attend these congresses as a private physician and not at government expense.

PUBLIC HEALTH SERVICE

EFFECT OF WAR ON CHILDREN

A \$20,000 research grant has been awarded to the International Committee on Mental Hygiene under the National Mental Health Act. Oscar R. Ewing, federal security administrator, has announced. The grant will be used to make a study of the effect of war on children. This study will be made under the direction of Dr. David Levy, professor of psychiatry, Columbia University, New York, and will be presented at the International Congress on Mental Health to be held in London, England, in August. The grant was recommended by the National Advisory Mental Health Council and was approved by the Surgeon General, U. S. Public Health Service.

RESEARCH ON WATER POLLUTION

The recent Water Pollution Control Act passed by Congress authorizes \$800,000 a year for the next five years to erect and equip building at Cincinnati for the use of the U. S. Public Health Service in research and study of water pollution and the training of personnel for the control of water pollution. The Cincinnati laboratory has been the national headquarters for water pollution research since it was established in 1913. The two principal sources of water pollution are domestic sewage and industrial wastes generated during manufacturing processes; for example, gas and coke plants, metal working shops and refineries dump acids, salts, brine and phenols into the water resources; meat packing and canning industries produce organic matter, and the synthetic rubber industry adds butadiene and styrene. More active research is needed because of the increasing pollution of water supplies from which people draw their drinking water.

The Water Pollution Act also authorizes a million dollars a year for the next five years to be granted to the states for

research, surveys and study on the prevention and control of water pollution caused by industrial wastes. The appropriation to carry out this act, the Public Health Service states, will be sought at the next session of Congress.

AWARDS AND COMMENDATIONS

Dr. Thomas Parran

In a ceremony in the office of the Secretary of the Army on September 3 the Distinguished Service Medal was presented to Dr. Thomas Parran Jr., formerly the Surgeon General, U. S. Public Health Service. The citation read as follows:

Dr. Parran, the Surgeon General, United States Public Health Service, performed exceptionally meritorious service in a duty of great responsibility to the government by extensive support to the Army in implementing civilian public health and medical service programs and aiding and advising in the development of the Army's preventive medicine programs from December 1941 to December 1946. With exceptional foresight, energy, initiative and outstanding spirit of helpful cooperation Dr. Parran's technical knowledge was applied administratively to insure solution of vast health problems in an economic and efficient manner resulting in worldwide success for the Army's health program in spite of major adversity and hazard. His advice and undaunted spirit as well as personal courage and capacity for eliminating frequent administrative obstruction aided in preventing any widespread health deficiencies among our own civilian and military population, those of liberated countries and allies, displaced persons, and enemy groups after they came under Army control. His efforts contributed materially to the successful prosecution of the war against the common enemy and reflect outstanding credit on himself and the government of the United States.

Medical News

(Physicians will confer in favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

ARKANSAS

University Appointments.—Harry J. Clausen, Ph.D., was appointed associate professor of the department of anatomy of the University of Arkansas School of Medicine, Little Rock, on July 1. Dr. Clausen is a graduate of the State University of Iowa and New York University. He was professor and head of the department of anatomy, Loyola University School of Dentistry, New Orleans, and formerly was associate professor of anatomy at the University of Colorado School of Medicine, Denver. James S. Dimming, Ph.D., has been appointed assistant professor in the department of biochemistry. Dr. Dimming received his Ph.D. degree in 1948 from Oklahoma Agricultural and Mechanical College, Stillwater. Dr. James O. Ferguson, Danville, a graduate of the Medical School, 1945, has been appointed instructor in the department of anatomy. Dr. Ferguson was discharged from the U. S. Army Air Corps in July 1948.

DELAWARE

State Medical Meeting.—The Medical Society of Delaware held its annual meeting at the Colony Club, Rehboth, September 13-15 under the presidency of Dr. Howard S. Riggins. Guest speakers included:

Fred W. Wittich, Minneapolis, Minn., Allergic Diseases.
John B. Montgomery, Philadelphia, Office Gynecology.
Hart E. VanRiper, New York, Poliomyelitis Research.
Thaddeus L. Montgomery, Philadelphia, Factors in the Low Mortality Rate in Obstetric Practice.
Clarence S. Livingood, Philadelphia, Diagnosis and Treatment of Foot and Hand Eruptions.
Russell Wigh, Philadelphia, Limitations of Roentgen Diagnosis.
Lawrence S. Carey, Philadelphia, Management of Cardiac Infarction.
Richard T. Smith, Philadelphia, Treatment of Arthritis.
John Z. Bowers, Washington, D. C., Use of Radioactive Isotopes in Clinical Medicine.
W. Paul Havens Jr., Philadelphia, Infectious Hepatitis.
John C. Ulery, Philadelphia, Delivery of Quadruplets by Caesarean Section.
Norman R. Ingraham Jr., Philadelphia, Intensive Therapy of Syphilis.
The address at the annual banquet was given by Dr. Brian Hunt Vavdry, Oxted, Surrey, England, on "Impressions of Socialized Medicine in England."

ILLINOIS

Resolution on Military Service.—The council of the Illinois State Medical Society has made public a resolution adopted recently urging young physicians to volunteer immediately for military service. The society pointed out that of the additional physicians needed by the armed forces before Jan. 1, 1949, Illinois probably will have to supply about 600. The society states that the resolution was directed especially at those young doctors who received all or part of their medical education at the expense of the government, under the wartime A.S.T.P. and V-12 programs, but who did not serve in the armed forces because the war ended before they had completed their courses.

Chicago

Relation Between Nucleus and Cytoplasm.—The American Cancer Society has awarded a grant of \$18,935 to the University of Illinois College of Medicine in support of cytochemical studies of relations between nucleus and cytoplasm. The studies will be conducted by the department of pathology, under the supervision of Isidore Gersh, Ph.D., associate professor of pathology.

The Ranson Lecture.—Dr. George M. Lyon, Washington, D. C., chief of the radioisotope section, department of medicine and surgery, Veterans Administration, will deliver the Ranson Lecture on "The Radioisotopes in Medicine," October 22 at 4:30 p. m. at the Archibald Church Library of Northwestern University Medical School. The lecture is sponsored by the Theta Chapter of Phi Beta Pi Fraternity. All members of the American Medical Association are invited.

Personals.—Dr. Max C. Igloe has been appointed head of the city health department's first district health center at 800 South Paulina Street, which will open when the whole staff has been chosen. Dr. Igloe, a veteran of World War II, has been director of outpatient services of the Veterans Administration in Chicago.
—Dr. James J. Callahan, chairman of the department of bone

and joint surgery of the Stritch School of Medicine of Loyola University, attended the congress of the International Society of Orthopaedic Surgery and Traumatology, September 13-18, at Amsterdam, Netherlands, as a delegate from the United States.

INDIANA

State Medical Meeting.—The annual meeting of the Indiana State Medical Association will be held at the Murat Temple, Indianapolis, October 26-28 under the presidency of Dr. Cleon A. Nafe, Indianapolis. Guest speakers at the general meeting will be:

Eugene B. Ferris, Cincinnati, Evaluation and Management of Hypertension.
John M. McLean, New York, Corneal Grafting.
Arthur C. Curtis, Ann Arbor, Mich., Sarcoidosis.
Ralph M. Tovell, Hartford, Conn., Role of Analgesics and Anesthetics in Production of Asphyxia Neonatorum.
Wingate M. Johnson, Winston-Salem, N. C., Need for Recognition of General Practice.
Herbert E. Schmutz, Chicago, Carcinoma of the Uterus.
Earl D. McBride, Oklahoma City, Disability Evaluation.
Hugh R. Rutt, Rochester, Minn., Present-Day Status of Tests of Hepatic Function.
William K. Keller, Louisville, Ky., Observation.
Isador S. Ravdin, Philadelphia, Vagotomy.
Paul R. Hawley, Chicago, Only Doctors Can Defeat the Socialization of Medicine.
Archie L. Dean, New York, Cancer of Genito-Urinary Tract.
Irving S. Wright, New York, Use of Anticoagulants in the Treatment of Diseases of the Heart and Blood Vessels.
Albert D. Kaiser, Rochester, N. Y., Virus Infections in Children.
Austin M. Bruce, Chicago, about atomic radiation in medicine.

Section meetings will be held Wednesday at 4:30 p. m. At a dinner sponsored by the Indiana Academy of General Practice Wednesday at 6 p. m. Dr. Johnson will be the speaker. The annual dinner speaker will be Dr. Ernest E. Irons, Chicago, President-Elect, American Medical Association. The Woman's Auxiliary to the association will meet October 26-28 at the Murat Temple.

KANSAS

Tumor Clinic.—The Sedgwick County Medical Society will hold a clinic at its October 19 meeting in Wichita, on "Malignant Tumors of the Respiratory System." Seven physicians will present ten minute papers on the subject.

Mental Hygiene Meeting.—The Kansas Society for Mental Hygiene meeting in Topeka, October 25, will discuss plans for legislative action, roles of laymen and others in promoting mental health and the development of an effective mental hygiene program.

Advisory Committee on Health.—The Sedgwick County Medical Society and the county and city commissioners have sponsored a new board to act in an advisory capacity to the city and county. The board, to be known as the Sedgwick County Medical, Hospital and Health Board, consists of eleven members, one each from the Board of County Commissioners, Board of City Commissioners, Wichita Board of Education, and a layman appointed by the Board of City Commissioners and six doctors appointed by the county medical association, subject to ratification by the boards of county and city commissioners.

MASSACHUSETTS

Seminar in Legal Medicine.—The department of legal medicine of the Harvard Medical School, Boston, is offering a seminar in legal medicine November 8-13 for pathologists, medical examiners and coroners. Lectures and demonstrations will deal with various problems likely to be encountered incident to the investigation of deaths in the interests of public safety and to the performance of medicolegal autopsies. The enrollment is limited to twenty-five and the fee is \$50. Application should be made on or before October 30 to the Department of Legal Medicine, 25 Shattuck Street, Boston (15).

Dr. Hyde to Open Health Forums.—Henry Van Zandt, Hydesville, Md., U. S. representative of the World Health Organization, will speak at the first of a series of "Health Forums" September 29 from 3:30 to 5:30 p. m. at the Peter Bent Brigham Hospital. The speaker at the first of a series held at the Harvard School of Public Health, limited seating capacity, it is through the Office of the Senior Surgeon of the U. S. Department of the Interior. In that capacity of American plans and policies of the World Health

MINNESOTA

Personal.—Dr. Olaf Mickelsen, Minneapolis, associate professor in the University of Minnesota's laboratory of physiological hygiene, has resigned to become chief of the biochemical section in the U. S. Public Health Service nutrition division in Washington, D. C. Dr. Mickelsen has been on the staff of the University of Minnesota since 1940.

The Rigler Lecture.—Dr. Merrill C. Sosman, clinical professor of radiology at Harvard Medical School, Boston, will deliver the annual Dr. Leo G. Rigler lecture in radiology at the University of Minnesota, Minneapolis, October 28 at 8 p. m. in the Minnesota Museum of Natural History auditorium on "Roentgenological Aspects of Heart Disease." This annual lectureship was established in 1944 by colleagues, former students and friends in recognition of Dr. Rigler's contributions to teaching and research in radiology. He has been chief of the department of radiology at the University of Minnesota Medical School since 1926.

NEW YORK

Postgraduate Lectures.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged postgraduate lectures as follows: The Onondaga County Medical Society will hear Dr. Leo M. Taran, New York, speak on "The Treatment of Rheumatic Fever" at the University Club, Syracuse, October 5 at 8:30 p. m. On October 30 Dr. Irl H. Blaisdell, Syracuse, will speak on "The Problem of Carcinoma of the Larynx" before the members of the Sullivan County Medical Society meeting at the Lenape Hotel, Liberty, at 8:30 p. m.

Courses in Psychiatry and Neurology.—The New York State Department of Mental Hygiene on September 10 opened resident courses in psychiatry and neurology at the Psychiatric Institute in New York City. The forty-eight weeks of formal instruction and clinical work is designed to recruit physicians for state mental hospitals. The fifty-three registered physicians in the course will be assigned for a two year period to the staffs of the various state hospitals for instruction and clinical practice. A similar course opened at Syracuse Psychopathic Hospital September 17. This program of training psychiatrists was started in 1946.

New York City

Changes in Long Island Faculty.—Sixty-one promotions and seventy-two appointments have been made at the Long Island College of Medicine, Brooklyn, for the coming year, increasing the faculty to about 500. The department of psychiatry, with its program of expansion, has twenty-six new faculty members; the department of medicine has eighteen new faculty members. Those promoted were Dr. Frank P. Light, former clinical professor of obstetrics and gynecology, to professor of clinical obstetrics and gynecology; Drs. Richard L. Frank and Edwin P. Falsey, former associate professors of clinical psychiatry, to professors, and Dr. Charles B. Jones, former associate professor of clinical surgery, to professor.

Annual Academy Graduate Fortnight.—The New York Academy of Medicine will hold its annual Graduate Fortnight October 4-15 on the subject, "Advances in Therapy." The program includes evening lectures, morning panel discussions, afternoon hospital clinics and scientific exhibits. Out of state speakers at the evening lectures include:

Austin Smith, Secretary, Council on Pharmacy and Chemistry, American Medical Association, Chicago, Safeguards in the Use of New Drugs.

Lauren H. Smith, Philadelphia, A Critique of the Physiological Methods in Psychiatric Therapy.

Robert P. Knight, Stockbridge, Mass., A Critique of the Present Status of the Psychotherapies.

Reginald H. Smithwick, Boston, Evaluation of Surgical Treatment of Hypertension.

Cyrus C. Sturgis, Ann Arbor, Mich., The Carpenter Lecture, Advances Concerning the Etiology and Treatment of Hematologic Disorders.

Louis K. Diamond, Boston, Treatment of Rh Hemolytic Disease of the Newborn.

Charles A. Janeway, Boston, Newer Use of Blood Fractions.

Bernard N. Halpern, Paris, France, Newer Knowledge Concerning the Antihistamine Drugs.

Richard H. Sweet, Boston, Surgical Treatment of Carcinoma of Esophagus.

James B. Blodgett, Boston, Early Ambulation Following Surgical Procedures.

Chester M. Jones, Boston, Treatment of Peptic Ulcer.

James H. Meats, Boston, Treatment of the Complicated or Neglected Case of Graves' Disease.

The registration fee for physicians other than fellows of the Academy of Medicine is \$6, payable to the New York Academy of Medicine, 2 East 103 Street.

PENNSYLVANIA

Benjamin Rush Award.—The Medical Society of the State of Pennsylvania has selected Alan Scaife of Pittsburgh, and the Rotary Club of Lancaster to receive its first Benjamin Rush Award, which was inaugurated to recognize the public-spirited citizens and organizations which have collaborated with the medical profession in the promotion of better health and medical care for all Pennsylvanians. Each county medical society throughout the state nominates a lay person and an organization from its area, and from these the board of trustees of the state society select the winner. Alan Scaife is a trustee of the Elizabeth Steel Magee Hospital, the Woman's Hospital, the Mellon Institute of Industrial Research, the Carnegie Hero Fund Commission, and the University of Pittsburgh. As a trustee of the university, he has devoted much time in furthering the development of the school of medicine and the hospitals comprising the University Medical Center. He served in both World Wars. The Rotary Club of Lancaster was selected for its part in the organization, development and maintenance of its Cleft Palate Speech Clinic, which not only corrects the defect in children with cleft palate but carries through in speech training and rehabilitation.

Dr. Benjamin Rush, for whom the award is named, was born near Philadelphia in 1743, and became one of the outstanding medical men in history. He was professor of the practice of medicine in the University of Pennsylvania, a founder of the Philadelphia College of Physicians, a signer of the Declaration of Independence, and a member of the Continental Congress.

TEXAS

Tumor Seminar.—A tumor seminar will be held at Brooke General Hospital, San Antonio, October 23, by the San Antonio Society of Pathologists. It will be conducted by Dr. Shields Warren, Boston, on "Tumors and Diseases of the Reticulo-Endothelial System." Twenty-five cases will be presented. All pathologists interested are invited to attend. There is no admission fee. Inquiries may be directed to Dr. B. F. Stout, Medical Arts Building, San Antonio.

WASHINGTON

Annual State Meeting.—The annual convention of the Washington State Medical Association will be held at the Olympic Hotel, Seattle, October 3-6 under the presidency of Dr. Albert J. Bowles, Seattle. The program has been arranged in symposiums followed by panel discussions on pediatrics, gynecology, thoracic surgery, surgery (intestinal obstruction), heart vessels, orthopedics, liver, roentgen therapy, common psychoses, found in general practice and ear, nose and throat. Guest speakers on the symposiums include: John Rock, Boston, The Physiology of Fertilization, and Frederick L. Reichert, Stanford University, Calif., Headaches, Tics and Neuralgias of the Head. At the dinner October 3 the guests will be Dr. Roscoe L. Sensenich, South Bend, Ind., President of the American Medical Association, Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, and Dr. John W. Cline, San Francisco, past president of the California State Medical Association. The Woman's Auxiliary will meet in conjunction with the state association.

WEST VIRGINIA

Research at the University.—The department of bacteriology and public hygiene of the West Virginia University School of Medicine, Morgantown, has received a grant from the division of research grants and fellowships of the U. S. Public Health Service to be used for the development of serologic methods for the identification and classification of Actinomyces bovis. The grant was made to John M. Slack, Ph.D., head, department of bacteriology, who has been interested in this problem for years. The department of pathology also received a U. S. Public Health Service grant of \$5,000 to be used to expand the cancer teaching facilities.

County Health Merger.—A tricity health unit, comprising Morgan, Berkeley and Jefferson counties, has been organized in the eastern Panhandle to take over the service of the part time health unit and nursing services in Morgan and Jefferson counties and to improve and extend health services in the three counties. Additional clinical services have already been arranged, and direct individual service will be provided where needed. A budget of \$57,000 has been fixed by the officials of the three counties. Part of this amount will be provided by the state health department with the aid of federal funds. Dr. Garnett P. Morison, Charles Town, who

has been largely responsible for effecting the merger of health services in the three counties, will serve as health director of the unit. He has been serving as part time health officer for both Berkeley and Jefferson counties.

WISCONSIN

Dr. Woolsey Appointed Professor of Physiology.—Dr. Clinton N. Woolsey of the Johns Hopkins University School of Medicine, Baltimore, has been appointed to the recently created chair, the Slichter Research Professorship of Physiology, at the University of Wisconsin Medical School, Madison. Dr. Woolsey, a graduate of Johns Hopkins University School of Medicine, has served his alma mater successively as assistant in physiology, instructor, assistant and associate professor in that department. In 1938-1939 he had an appointment as Rockefeller Fellow at the Eldridge Reeves Johnson Foundation for Medical Physics and a Fellowship in Neurology, both at the University of Pennsylvania. The Wisconsin Alumni Research Foundation established the Charles Sumner Slichter Research Professorship in the Natural Sciences as a memorial of the late Professor Charles Sumner Slichter.

Course in General Medicine.—The University of Wisconsin Medical School, Madison, is presenting an Intensive Course in General Medicine, October 18-22, at the State of Wisconsin General Hospital and the medical school. The course will comprise lectures, didactic work and ward rounds, and case demonstrations. The anemias, diabetes, dermatologic conditions, pulmonary disabilities, gastrointestinal pathology, newer drugs and diagnostic methods will be included in the material offered. This course will be under the general direction of Dr. Ovid O. Meyer, chairman of the department of medicine. Maximum registration will be fifteen physicians and the minimum eight. The fee will be \$25. Application should be made immediately to Dr. Llewellyn R. Cole, Coordinator of Graduate Medical Education, The Medical School, 418 North Randall Avenue, Madison (6).

GENERAL

Ambulatory Fracture Association.—This association will hold its annual meeting at the Mayflower Hotel, Washington, D. C., October 4-6 under the presidency of Dr. Homer D. Junkin, Chicago. The meetings are open to members and guests for discussion of fracture cases and problems, and all surgeons are invited to attend. The dinner speaker will be Dr. Joseph M. Murray, Ottawa, Ontario, Canada.

Special Society Meeting.—The annual session of the American Otorhinologic Society for Advancement of Plastic and Reconstructive Surgery, Inc., will take place at the Palmer House, Chicago, October 9, beginning at 6 p. m. Dr. Wayne B. Slaughter, Chicago, will speak on "Alar Deformity Due to Hare Lip" and Dr. Bert E. Ellis, Indianapolis, Ind., on "Problems of the Beginner in Rhinoplasty." Dr. Jacob Daley, New York, is president of the society.

Meeting of Maxillofacial Surgeons.—The annual meeting of the American Society of Maxillofacial Surgeons will be in Ann Arbor, Mich., September 26-29. Surgical clinics will be held each morning at University or St. Joseph's hospital. Subjects to be discussed include blood loss in surgery of cleft lip and palate cases, treatment of mandibular deformities following removal of nonmalignant tumors, water and protein balance in preoperative management of maxillofacial cases and The annual dinner will be held at Club Tuesday at 7 p. m.

Lost Narcotic Order Forms.—The Office of the Commissioner of Narcotics, Washington, D. C., has submitted to importers, manufacturers and wholesale dealers in narcotics the serial numbers of a great many order forms for opium and other narcotics which have been lost or stolen and which may possibly be in the hands of persons not entitled to them. Importers, dealers and manufacturers are cautioned not to fill any order for narcotics on which one of the serial numbers listed appears and to forward any such order form received at once to the Office of the Commissioner of Narcotics.

Meeting to Honor Dr. Béclère.—The American Society for the Study of Sterility, Eastern Section, will hold a special meeting open to members of the medical profession to honor Dr. Claude Béclère of the Hospitals of Paris, France. Dr. Béclère, a pioneer in the field of gynecological roentgenology, will deliver a paper on "Hysterosalpingography and Sterility," October 1 at 8:15 p. m. at the New York Academy of Medicine, 103rd Street and Fifth Avenue. Since seating capacity is limited, those desirous of attending are urged to write immediately to The American Society for the Study of Sterility, Eastern Section, Suite 102, 1160 Fifth Avenue, New York (29), for a ticket of admission.

Proctologists Meeting.—The annual meeting of the National Proctologic Association will be held at the Brown Hotel, Louisville, Ky., October 6-8 under the presidency of Dr. Paul S. Osborn, Louisville. Besides numerous papers to be presented there will be an operative clinic Thursday and Friday mornings. The president's reception and annual banquet will take place Wednesday evening, with Dr. Alfred J. Cantor, Flushing, N. Y., giving the address on "Ambulant Proctology." The registration fee for non-members is \$10 unless one has registered before, in which case it is \$25, the regular membership fee.

Science Writing Award.—The Westinghouse Science Writing Awards of \$1,000 each were presented by the American Association for the Advancement of Science at its recent annual meeting to Frank Carey, science reporter in the Washington Bureau of The Associated Press, and Florence Moog, Ph.D., assistant professor of zoology at Washington University, St. Louis. Mr. Carey, a newspaper man for seventeen years, was granted the best newspaper science writing award for a four part series, "Newest Wonder Drug Conquers Dread Scrub Typhus," distributed by The Associated Press. Dr. Moog received the best magazine science writing award for an article on "The Biology of Old Age," which appeared in the June issue of *Scientific American*. The purpose of the George Westinghouse Science Writing Awards is to encourage high standards of science writing in newspapers and magazines and to stimulate interest in young writers in making a career of science writing. The awards competition are administered by the American Association for the Advancement of Science.

Incidence of Poliomyelitis.—According to the U. S. Public Health Service as of September 9, the largest weekly total of reported cases of poliomyelitis this year was recorded for the week ended September 4—1,512 as compared with 1,412 the previous week. The five year median for the week is 956 cases. Increases of 10 or more cases (aggregating 134 cases) were reported in seven states, as follows (last week's figures in parentheses): California 264 (226), Illinois 87 (62), Indiana 29 (19), Tennessee 34 (18), New York 101 (87) (decline in New York City from 52 to 49), South Dakota 21 (10) and Kansas 28 (18). The incidence increased slightly in North Carolina from 133 to 138 but declined in Texas from 71 to 52. Only nineteen states reported more than 20 cases for the week ending September 4 and only 25 states reported more than 100 cases to date. Total cases reported to date are 12,666, as compared with 3,834 in 1947, 12,434 in 1946, and a five year median of 6,156 for the corresponding period. Although more cases have been reported to date than for the corresponding period in 1946, and the peak week of 1946 came earlier than usual, i. e., the week ended August 17, a prediction at this time regarding the final figure for this year would be hazardous, as the rate of decline following the peak week is not constant. In 1946 the decline was rather slow, and almost twice as many cases were reported after the peak week as up to the end of that week, while in 1944 the numbers of cases were approximately equal for the two periods, and in 1947, 1945 and 1943 more cases were reported during the first period.

Marriages

FRANKLIN ROBERT SMITH, Milwaukee, to Miss Lenore Anderson of River Falls, Wis., at Rochester, Minn., June 5.

BEECHER WILLIAM LEVERSEE, Rexford, N. Y., to Miss Charlotte Ann Fegan of South Bend, Ind., June 19.

FLETCHER ALLEN MILLER, Iowa City, to Miss Barbara Leontine Sheridan at Hartford, Conn., June 12.

GLENN WALTER PENNINGTON to Miss Mary Justine McDevitt, both of Charlotte, N. C., May 8.

MICHAEL R. SCULLY to Miss Mary Louise McQueeney, both of Bridgeport, Conn., May 15.

HUNTER MERRILL BROWN to Miss Caroline Tardy Matthews, both of Birmingham, Ala., May 5.

PAUL KARLIK JR., Hazelton, Pa., to Miss Elizabeth Jane Rineard of Harrisburg, June 25.

JOHN LOTT BOYER, Arendtsville, Pa., to Dr. MARY FRANCES VASTINE of Philadelphia, June 2.

ROBERT CANNON SAMPLE to Miss Frances Lyle, both of Hendersonville, N. C., May 1.

RAYMOND EVERETT MILLER, Trenton, N. J., to Miss Enid Fenton of New York, May 16.

International Conference on Mental Hygiene

Over 1,600 delegates from forty-six nations attended the International Conference on Mental Hygiene. It made a new departure at such international gatherings by tackling the most important problem faced by medicine, the treatment of a sick world, so as to promote good feeling among nations. Lord Addison (once an anatomist), who was the first Minister of Health in this country, spoke on behalf of the Government. He said that advances in the physical sciences had presented the world with its greatest question, whether we should make the best use of the physical powers provided by science, or allow them to be prostituted by war. Wars begin in the minds of men, and it is in the minds of men that the defences of peace must be constructed.

Mr. R. A. Butler, M.P., president of the National Association for Mental Health, said that there is more unknown territory to explore in the mind of man than remains undiscovered on the terrestrial globe. Moreover, the minds of men are thrown out of balance by the recent war and economic distress. Even in countries whose ways of life and belief appear to be intact, the most ordered and disciplined intellects are appalled that man is a prey to engines of destruction which he was proud to invent but is now unable to control.

Dr. F. Fremont-Smith, vice president for the United States of the International Committee for Mental Hygiene, said that today there is available new knowledge of the forces which impose on groups unhealthy attitudes which constrict, distort and hide from view the great capacities for love and affection, for friendship and cooperation, which are natural to all human beings. Can man's increasing knowledge of his own behavior save mankind?

Professor Henrique Roxo, of the University of Brazil, said that abnormalities in action are often the testimony of mental illness. Interpreting the facts that followed war, one cannot be surprised if, instead of peace and tranquillity, one finds unjustifiable revolutions, unnecessary strikes, attitudes of aggressiveness and sometimes an unbelievable tendency to suppress the freedom of man.

Dr. Carl Binger, of Cornell University, said that chief concern of the Congress should be the prevention of war. The greatest of all human problems cannot be solved by moral exhortation. We need to know more about the transmission of war fever, how the infection spread and why it is no longer a localized endemic but so quickly reached pandemic or global proportions. We need to know how to isolate the source of infection. Medical and social students who specialize in the study of man and his relations must marshal all knowledge and our best intelligence to grapple with the problem of how to prevent war; how to interfere at every possible point with its spread.

International Congress on Child Psychology

Representatives of fifty-three nations assembled in London for the International Conference on Child Psychology as part of the International Congress on Mental Health. Dr. F. H. Allen, president of the Orthopsychiatric Association of America, opened a discussion on aggression in relation to emotional development. He said that the basic birthright of every child is to become through his own experience an individual in his own right. The more devastating frustrations develops through denying the child the support which he needs to achieve a healthy sense of himself in the culture into which he was born. Overpossession and protection of the child from all anxiety, holding

him in the vise of parental care, frustrate the growth potential, paralyzing aggressive action in early years, and might lead later to desperate efforts to cut the ties which bind parents and child together. The more a child can be helped to live out in real life the feeling which arises in the growth process, the healthier will be the result, but there remains an important place for fantasy in every child's life.

Gram-Negative Bacteria of the Respiratory Tract

Drs. Castex, Capdehourat and Rechniewski reported before the National Academy of Medicine their investigation of 378 strains of gram-negative bacteria isolated from 1,000 samples of subacute and chronic processes, localized in different parts of the respiratory apparatus (41 from nasal fossas, 123 from paranasal sinuses, 55 from pharyngeal secretion, 129 from sputum, 30 from pus of pulmonary abscesses and of pleurisy). The bacterial species found were *Escherichia coli* (26 cases), *Proteus vulgaris* (48 cases), *Aerobacter aerogenes* (20), *Klebsiella pneumoniae* (239), *Pseudomonas aeruginosa* (20), and 23 which could not be classified. This investigation discloses that in comparison with observations made before the era of the antibiotics and sulfonamide drugs the gram-negative bacteria have increased in frequency and quantity. Their abundance is apparent not only from the diminution of gram-positive bacteria, but also from a real increase in the gram-negative. This is related to the use of antibiotics and sulfonamide compounds which have a known influence on the gram-positive flora. The authors advise not to use any antibiotic treatment in infectious diseases of the respiratory tract, as trivial as they may seem to be, without knowing previously the nature of the responsible germs and the degree of their sensitivity to the medicament which presumably would be efficient. When such diseases continue for a long time in spite of treatment, periodic bacteriologic examinations should be carried out to find out the influence of the administered drug. According to the authors, the extraordinary use made of penicillin has determined the increase of the chronic refractory processes, originated, at least partly, by the gram-negative bacteria which are insensible to its action. For this reason, it would not be wise to treat a patient exclusively with penicillin or sulfonamide compound, when a primary or secondary gram-negative flora exists, and particularly when it is prevailing. Penicillin and sulfonamide compounds must therefore be used with great caution.

Furthermore, the authors observed that in the serious respiratory diseases of putrid and gangrenous character, the gram-negative bacteria coexist constantly with the anaerobic germs. The gram-negative germs are the most difficult ones to extinguish therapeutically; often they are the residual flora which is responsible for the incurability of a chronic process. If antibiotics are used against these gram-negative germs, it must be done from the beginning in efficient, elevated doses. In many cases streptomycin is preferable to penicillin. The mentioned species of gram-negative bacteria frequently cause intense cutaneous reactions together with others of symptomatic focal type (allergic). The gram-negative germs, especially *Esch. coli*, produce penicillinase, which inactivates penicillin. With the increase of the gram-negative germs the production of penicillinase also increases, thus decreasing more and more the effect of penicillin.

Persistent Paroxysmal Ventricular Tachycardia

Drs. F. V. Gaspary, P. R. Tuero and R. Garcia Turiella of Rosario observed a male 18 years old who presented, as initial symptom of a general infectious process, paroxysmal ventricular tachycardia.

The electrocardiogram evidenced alterations of form of the ventricular complexes of ventricular paroxysmal tachycardia.

during the different days, with four types of complexes which appeared in irregular succession. This tachycardia presented retrograde ventriculoauricular conduction, at the beginning regular and later on with incomplete block of the type 2/1. The tachycardia disappeared when high doses of quinine (for lack of quinidine) were given, but reappeared each time immediately after the administration of the drug was diminished or increased. When the rhythm became regular the post-tachycardiac syndrome appeared, and furthermore P waves of high voltage, which are considered a part of this syndrome. The tachycardia is interpreted as a manifestation of the infectious process the etiology of which is unknown. The patient died of an unknown infection of peritoneal type.

Brief Items

Prof. Dr. C. Bonorino Udaondo has been elected president of the National Academy of Medicine for 1948-1949.

The Argentine Government has given 36,000,000 pesos to the City of Buenos Aires for improvement of the hospital services.

GERMANY

Aug. 24, 1948.

Medical Mission to Germany

To fill the gap in the German academic world which the Hitler régime left by isolating Germany from the rest of the world, the Military Government promotes the reestablishment of contacts with members of the German medical profession and the exchange of information on medical advances made during the past ten years.

Sponsored by the Cultural Affairs Adviser to the Military Governor and the Education and Cultural Relations Division, Office of Military Government, United States, the Unitarian Service Committee, the Service Branch of the Unitarian Church of America, sent a medical mission to Germany headed by Dr. Krayer, German-born head of the department of pharmacology, Harvard Medical School. The group consists of Drs. Dallas B. Phenister, vice chairman of the mission, professor emeritus of surgery, University of Chicago; Howard C. Taylor Jr., professor of obstetrics and gynecology, Columbia University College of Physicians and Surgeons, New York; David G. Cogan, director of the Howe Laboratory of Ophthalmology, Harvard Medical School; Herman De Wilda, instructor in clinical dentistry, Harvard Medical School; John T. Esdall, associate professor of biological chemistry, Harvard Medical School; George Keble Hirst, chief of the division of infectious diseases, Public Health Research Institute, New York; Francis D. W. Lukens, director of the George S. Cox Medical Research Institute, University of Pennsylvania; Benjamin H. Robbins, head of the department of anesthesiology, Vanderbilt University School of Medicine, Nashville, Tenn.; Carl F. Schmidt, professor of pharmacology, University of Pennsylvania School of Medicine; Erwin W. Strauss, director of professional education and research at Veterans Hospital, Lexington, Ky.; Joseph F. Volker, dean of the Tufts College Dental School, Boston; William M. Wallace, assistant professor of pediatrics, Harvard Medical School, and Friedrich Wassermann, professor of anatomy, University of Chicago.

Thus far, the group has lectured in Frankfurt, Berlin, Goettingen and Munich. It will visit Tuebingen, Freiburg and Heidelberg before leaving for New York early in September. The mission was unable to enter the Russian Zone, but has made contacts of an informal nature with German medical scientists in the Russian as well as in the United States, British and French sectors of Berlin.

According to Dr. Krayer, the biggest surprise of the German doctors was expressed with respect to the large scale of blood

banks and transfusions in the United States. They were eager to learn about the technics employed in that field.

The mission not only has benefited German medical science but has also contributed to the lifting of the morale of the German medical profession by demonstrating that the United States is eager to resume normal professional and cultural relations with Germany.

Nutrition in Western Germany

Now, two months after the introduction of the currency reform in Western Germany, it can be stated that it has had a most beneficial effect on the food situation. There was no unrationed food available on the market prior to the new currency. Almost overnight this picture changed radically. Fresh fruit and vegetables appeared in stores and market places and found ready buyers. The population was so stunned by this miracle-like change that people spent their *Kopfgeld* (45 German marks which were given to each person who turned in the equivalent amount of old currency) for buying unrationed food irrespective of its high prices. In the weeks following, they became more conscious that they could not long afford to pay these prices, and buyers' strikes, organized by the trade unions, started all over the zones. They continued for about two weeks. The result of these strikes was a general lowering of the price level, between 10 and 50 per cent. Only yesterday, this correspondent spent an hour in roaming through the fruit and vegetable market of the once famous, now partly destroyed, but nevertheless bustling city of Wiesbaden and found an abundance of plums, pears, apples, tomatoes, onions, cucumbers, cabbage, lettuce and many other edibles at reasonable prices, a thing absolutely unheard of in Germany only two months ago.

The crop, owing to the favorable weather during the summer, is abundant. The rationing of potatoes, Germany's most important staple food, has been lifted as of August 18, and there is reason to believe that bread and flour will shortly be taken off the ration list. A great scarcity continues in meat, fats and milk, but it can fairly be stated that in Western Germany the food situation has tremendously improved since the currency reform. The barriers between the three Western zones have been lifted for Germans as of August 20, and persons and goods can freely circulate between the United States, British and French zones. This, too, cannot fail to influence favorably the recovery of Western Germany.

Medical News from Berlin

Unlicensed Doctors Detected.—Since the end of the war, the Berlin bureau of health has detected and had punished 128 persons who practiced medicine without license. During the same time, 40 physicians, 11 midwives and 1 nurse were indicted for illegal abortions. Fifty persons, among them 35 physicians, were punished for violations of the narcotic law.

Infectious Diseases in Berlin.—This is a review of the most important infectious diseases (number of new cases) in Berlin since the end of the war:

	Typhoid	Dysentery	Polio-myelitis	Syphilis	Gonorrhea
Second half of.....1945	16,66	15,182	55		
1946	3,475	3,125	89	12,978	32,841
1947	1,084	1,821	2,426	9,007	18,533
January.....1948	46	28	29	647	1,537
February.....1948	41	28	17	562	1,714
March.....1948	38	45	12	448	1,135
April.....1948	39	26	24	482	1,414
May.....1948	49	48	9	557	1,279

The numbers for May are not complete. There were 2,995 new cases of tuberculosis reported in April, as compared with 2,515 in March; 561 Berlin residents died from tuberculosis in April.

Correspondence

MEDICINE AND THE ARMY

A Letter from the Surgeon General of the Army

To the Editor:—In THE JOURNAL of Aug. 7, 1948, there appeared an editorial on "Medical Service with the Armed Forces." Increased interest in this subject is evidenced by various editorials and other comments in newspapers throughout the country. The editorial touched on a host of considerations arising out of the recent war, the contemporary situation, and more particularly those precipitated by the passage of the Selective Service Act by the 80th Congress. Inevitably the editorial approached the analysis of these problems from the viewpoint of organized medicine. Perspective is always a question of the position of the viewing subject to the perceived object. For this reason I welcome the opportunity to place before civilian medicine the picture as seen by the Army.

There is no point, if one is interested in solving a problem, to make it difficult when in essence it is simple. Now the problem that faces the armed forces at present, as far as medical care is concerned, is remarkably simple, no matter how difficult it may be to work out a satisfactory solution.

Even before the passage of the recent peacetime Selective Service Act the combined size of the Army and the Air Force had been set for occupation duties at approximately 1,000,000—more than five times the size of the prewar military establishment. The Medical Corps of the Regular Army was not permitted to recruit new members during the war, so that its size at the end of the war was actually smaller because of death and retirement than it had been at the outbreak of hostilities.

The corps has grown but not nearly fast enough to keep pace with the vastly increased requirements precipitated by the more than fivefold expansion in the combined strength of the Army and Air Force. Until now the situation did not reach crisis proportions. This was because the Army was permitted to retain on active service, or call to active service for a tour of duty of about two years, recent graduates of medical schools who had been deferred from wartime service. This deferment enabled them to complete their medical education, and this education was in most cases paid for in whole or in part by the Government. The wartime legislation which obligated this group (ASTP students) for two years of Army service was terminated by law in June 1946, and was limited to graduates before that date.

Informed individuals have known, however, that a critical situation was in the making which would sooner rather than later force the country to decide between a basic revision in its military policy and the devising of extraordinary measures to provide the armed services with adequate medical personnel. Congress was put on notice not once but repeatedly that the situation was deteriorating at an alarming rate and that by early 1949 the crisis would be upon us. Indicative of Congressional concern with the problem was the passage of legislation in the summer of 1947 which provided extra remuneration for doctors and dentists in the armed services, on the assumption that such a salary increase would facilitate procurement and reduce attrition. The shortage of medical personnel at that time was about to jeopardize our occupation policy.

Now that the Selective Service Act has been passed, the shortage threatens to nullify the basic principles of American security. This act increases materially the size of the Army

and Air Force but makes no provision for increased medical support.

It is inconceivable that the American public will permit a specific personnel shortage to endanger its security. Nor will it tolerate a solution based on a deliberate deterioration in the quality of medical service provided for men in the armed forces who are serving at home and abroad. There is a specific provision in the Selective Service Act which states that no man may be inducted until provision has been made for adequate medical care.

The armed forces have a responsibility to do their utmost to conserve such a valuable and scarce resource as medical personnel. It is gratifying to note that the strenuous efforts that the Army Medical Department has made since the end of the war to operate efficiently and economically were pointed out in your editorial. We have been working intimately over the past year with our civilian consultants who are leaders in American medicine, to insure that we benefit from their advice and counsel in keeping our medical standards at the highest level and in estimating our requirements. We hope that the American Medical Association will avail themselves of our invitation to review critically our estimated requirements. We have cut these requirements as low as we believe possible, but we will not cut our medical standards.

At the time of the Congressional hearings on the Selective

Service Act, the Army requested permission to draft certain categories of doctors for short tours of duty with the Army. This request was based on the knowledge that the medical resources which it had available would soon be inadequate to support the current strength, not to mention the increases which would follow the passage of the draft.

It seems a reasonable prediction that the Army for the present and the immediate future will in some degree embrace for a limited period a goodly

proportion of the young men and perhaps the young women in our nation. The ability to assume military responsibilities has become a citizenship function. Without dwelling in further detail on this important trend which must affect the medical profession, it is apparent that we must adopt new concepts and pursue new methods and realize that the military medical mission has become more than ever before a civilian medical mission. It has become increasingly evident that our own Regular Army career officers could not and should not be in sufficient numbers to completely staff a growing citizen Army. The nucleus which they form must be supported by numbers of doctors on temporary service.

The growth of the permanent corps of career medical officers is proceeding but its completion to full strength will not be evident for two or three years. This is because of the residency training period required in civilian hospitals over and above residencies available in Army hospitals. In our effort to make an Army career medically attractive to the medical graduate there have been fundamental changes and reforms in the structure and function of the Medical Department. These have been planned and accomplished with the active support and intimate cooperative efforts of many leaders in American medicine. They include among other things provision for career planning, a system of continuing postgraduate education, and the integration of civilian physicians as visiting men and teaching consultants in our major hospitals in this country and abroad.

The present emphasis on the economic aspects of military service is understandable as your editorial pointed out. Inflation has affected our entire population. One can hope that an economic balance will be worked out soon. Very naturally this

Physicians interested in serving on active duty for periods of at least six months or for longer periods and physicians who are interested in full time or part time medical service on a civilian status with the Army Medical Department are requested to write to The Surgeon General, U. S. Army (Personnel Division), Washington 25, D. C.

economic aspect plays its role in our procurement problem. However, I like to believe and I do believe that medical tradition is based on a loftier pledge than high remuneration.

In the last year or more since we have been able by law to increase our size we have commissioned 600 physicians on an active duty status in the Regular Army. Our standards for admission have been high and they have not and will not be lowered. When one realizes that the prewar corps totaled less than 1,200 this gain may be viewed approvingly.

The key to the situation, however, is not a comparison between what we now have and what we used to have, but rather between what we now have and what we now need.

Because more than 2,000 doctors now serving on temporary duty in the Army will be returned to civilian life during the coming year and because of the contemplated increase in size of these forces due to the Selective Service Act, the Army (including the Air Force) must secure about 4,000 physicians between now and June 1949. Since there is nothing in our experience to encourage us in the belief that such a large number could be secured by voluntary means, the Army requested permission to draft certain categories of doctors for temporary service, particularly the group of young men who were permitted to complete their medical studies during the recent war and have as yet rendered no service to the Government even though the majority of this group received liberal governmental stipends.

Statements about the size of this group have appeared in medical publications, and their numbers have been greatly overestimated. After allowance is made for the attrition for physical disabilities and essential work, it is doubtful whether the remaining number would exceed 3,000. Of these, only about 2,000 will have completed a year's internship by June 1949. It should be remembered here that none of these 3,000 are obligated by any existing law for service for any period of time with the armed medical services.

But the problem confronting the Army is not solely one of numbers. It also has a qualitative aspect. We are still very short of specialists, despite our refresher training and our comprehensive postgraduate training. In a recent communication, I pointed out to the President of your Association that approximately 400 of the required 4,000 doctors who had to be procured before July of next year should be specialists. I further stated that these 4,000 doctors with the included 400 specialists were required in staggered numbers over the coming months.

Time is running out. In opposing the draft of doctors representatives of organized medicine contended that the requirements of the armed forces could be met through voluntary rather than coercive methods. The officers of your organization have repeatedly stated that they would cooperate in every possible way in making this voluntary effort a success. I regret to say that up to this time the situation is not encouraging. As far as we can see, there has not been the slightest increase in procurement of doctors for temporary service since the passage of the draft. Clearly, if American medicine is desirous of avoiding governmental control over the procurement of physicians for the services it is not enough to attack such control—it must provide a concrete alternative. To date no such alternative has proved itself successful. One concrete suggestion that might prove feasible is to seek the voluntary cooperation of universities and other institutions in meeting the Army's requirement for specialists by granting leaves of absence to one or two members of their staff, preferably for one year—possibly for six months.

The Medical Department of the Army is not involved per se in the political or economic philosophy of medical care. It has a specific obligation to furnish medical support to the Army and Air Force of the United States. Clearly, it cannot furnish such support unless it has adequate numbers of properly quali-

fied doctors. It has done, and always with the advice and in the closest cooperation with the leaders in civilian medicine, what it can to make the Medical Department efficient and thereby attractive. This is continuing.

The problem is indeed simple. The American Government has decided on a program of defense and security that requires large numbers of men to serve in the armed forces. But clearly these men cannot be expected to serve unless they are provided with adequate medical care. The Medical Department of the Army has the responsibility for operating the system whereby such medical care is provided. Only civilian medicine can make available the doctors required to operate the system. Not only the Army, but the American public is eagerly awaiting the response of the civilian medical profession.

R. W. BLISS,
Major General
The Surgeon General.

EN. NOTE:—The American Medical Association has been one of the groups to urge on the President of the United States and on various government agencies, including congressional committees and the armed forces, the pressing need for the establishment of a civilian medical advisory committee to the National Security Resources Board to consider the medical needs of the nation and a joint civilian and military advisory committee to the Secretary of Defense to study the needs and consider sound policies for the medical services of the armed forces.

It appears that now these two advisory groups are about to become operative. This will place the Council on National Emergency Medical Service of the American Medical Association in a much better position to render sound opinions and advice to the medical profession as to how many additional doctors the armed forces must have during this peacetime period of expansion and how many doctors might be spared without resulting in serious shortage of physicians for the civilian population at large if war should come.

RABIES DIAGNOSED BY INOCULATION OF SALIVA INTO ANIMALS

To the Editor:—In THE JOURNAL, Jan. 24, 1948, page 253, appeared an editorial on rabies. The proof of the isolation of the virus from saliva has not been furnished for the first time, as described on page 254, but had already been established repeatedly thirty years ago. The works by Bertarelli and Volpino (*Morphologische und biologische Beobachtungen über einen Fall v. Wutkrankheit bei Menschen, Zentralbl. f. Bakt. [Abt. 1] 35:221*), Bertarelli (*Experimentelle Untersuchungen und Beobachtungen über die Tollwut, Zentralbl. f. Bakt. 39:399*), Herrmann (*Lyssa-Virus im menschlichen Speichel, Ztschr. f. Immunforsch. 58:389, 1928*) and Palawandow and Serebrennaja (*Über das Wutvirus im menschlichen Speichel, Ztschr. f. Immunforsch. 71:350, 1931*) should be referred to. These authors found the virus frequently, but not regularly, in the salivary glands of human beings. Special attention should be directed to the information in the book by Kraus, Gerlach and Schwarzenberg (*Lyssa bei Mensch und Tier, Berlin, Urban & Schwarzenberg, 1926*) and especially to the work by Schwarzenberg (*Neuere Ergebnisse der Tollwutforschung, Ergebn. d. Hyg., Bakt., Immunitätsforsch. u. exper. Therap. 20:1-154, 1937*).

In the two last-mentioned works are included reports of cases and literature dealing with positive infections induced in animals used for vivisection purposes from the virus obtained from the saliva of persons who died of rabies.

Medical Economics

OLD AGE AND SURVIVORS INSURANCE

Frank G. Dickinson, Ph.D., Director, Bureau of Medical Economic Research

In April 1948 the Advisory Council on Social Security submitted a report to the Senate Committee on Finance recommending expansion of the old age and survivors' insurance program. The Council found three major deficiencies in the existing system—inadequate coverage, unduly restrictive eligibility requirements and inadequate benefits. The proposed remedies included the immediate extension of coverage to self-employed persons, farm and household workers, employees of nonprofit institutions, federal civilian employees, railroad employees, members of the armed forces and employees of state and local governments; a lowering of the requirements for insured status to permit a larger proportion of older workers to qualify for benefits, and a liberalization of primary and family benefits, to apply to both present and future beneficiaries. The Advisory Council estimates that the level premium cost of its proposed program would be between 4.9 and 7.3 per cent of covered payroll as compared with an estimate of from 3.3 to 5.6 per cent for the present system. The expansion would be financed by an increase in employer and employee contribution rates from 1 to 1½ per cent of wages, to go into effect when benefits were liberalized. A subsequent increase to a 2 per cent rate and the addition of government contributions would be postponed until necessary to meet current costs of the program.

One month after submitting its proposals for the expansion of old age and survivors' insurance, the Advisory Council sent a second report to the Senate Committee on Finance recommending the adoption of a permanent and total disability insurance program. Of the Council's seventeen members, fifteen supported a strictly circumscribed program, to be integrated with old age and survivors' insurance and to cost an estimated 0.1 to 0.25 per cent of covered payroll. The remaining two members favored a plan of state assistance for the totally disabled involving federal grants.

Summary of Majority Recommendations

1. To qualify for disability benefits, an otherwise eligible person should be required to have (a) a minimum of 40 quarters of coverage, (b) 1 quarter of coverage for every 2 quarters after 1948 or attainment of age 21 and prior to the first quarter of total disability, (c) 6 quarters of coverage within the 12 quarters preceding the disability, and (d) 2 quarters of coverage within the 4 quarters preceding the disability.

These requirements are designed to insure that benefits would be paid only to persons recently and substantially attached to the labor market and consequently suffering loss of earnings due to disability. Retroactive payments would be limited to the six month period preceding the filing of a claim.

2. For purposes of the program, "permanent and total disability" would be defined as "any disability which is medically demonstrable by objective tests, which prevents the worker from performing any substantially gainful activity, and which is likely to be of long-continued and indefinite duration." Qualified persons would receive their first benefit after a waiting period of six months.

The strict definition of compensable disability and the long waiting period are intended to discourage would-be malingers who might give up work in order to qualify for benefits. Unlike many disability insurance plans, the proposed program does not assume permanency after a specified period of total disability and does not compensate workers who retain substantial earning capacity in any occupation.

3. The primary benefit would equal 50 per cent of the first \$75 of average monthly wage and 15 per cent of the remainder

up to \$275. No benefits would be paid to dependents of disabled workers.

Under the proposed formula, disability benefits would average about 30 per cent of average monthly wage up to \$350 and would in no case exceed one half of average monthly wage. Family benefits were excluded in order to preserve the economic incentive to self support.

4. Claims would be disallowed if the claimant refuses to submit to medical examination. Beneficiaries would be reexamined at least once a year; payments would be terminated if the beneficiary refused reexamination or was found to be fit for gainful employment.

5. Permanent and total disability insurance benefits would be suspended for any period in which Workmen's Compensation benefits are payable; disabled workers eligible for benefits under the proposed program and another federal disability program would receive only the larger benefit.

6. The effective date for payment of first benefits under the disability insurance program would be one year after the effective date for extension of coverage under old age and survivors' insurance.

The proposed postponement is designed to permit the Social Security Administration to solve the problems of coverage extension before tackling the administration of disability insurance. Moreover, the delay would allow time for preparation of regulations and procedures, recruitment and training of personnel, and education of the public in its new rights under the program.

7. Rehabilitation services would be furnished to disability insurance beneficiaries when it is probable that they will assist the beneficiary to return to gainful work.

The Council recommends the use of facilities set up under the current federal-state rehabilitation program. Payments from the old age and survivors' insurance trust fund would be made to state rehabilitation agencies in return for medical and surgical treatment and vocational retraining of disability insurance beneficiaries. These services are designed to reduce the ultimate cost of the program and to benefit the national economy by increasing the labor force.

The administration of permanent and total disability insurance, as pictured by the Advisory Council, would make use of the decentralized machinery set up under old age and survivors' insurance. Field offices, regional staffs and area offices would handle claims, while the central authority would limit itself to the supervision of policy. Old age and survivors' insurance wage information would be used to determine insured status and amount of benefits under the disability insurance program; periods of total disability would not be counted in computing retirement and survivors' benefits. All claimants would undergo a medical examination, conducted through federal facilities where available or through contract arrangements with private physicians, clinics and state and local hospitals. Physicians would be paid on a fee basis, and regional or area medical representatives would maintain relations with local practitioners. Area offices would evaluate and review the claimant's disability in terms of his capacity for gainful activity and would determine the frequency of reexamination. Claimants recommended for rehabilitation would be referred to the state rehabilitation agency, which would report progress to the social insurance system; benefits would be suspended if the claimant refused rehabilitation measures.

Criticism of Proposals

The Advisory Council's report includes a memorandum of the dissent by two of its members who favor provision for total disability through state assistance. Attention is called to the fact that the states already have agencies close to the disabled in their homes, with facilities for retraining, rehabilitation, reemployment and institutionalization. The suggested state plan would emphasize medical and vocational retraining rather than cash benefits, and would be financed by local tax funds supplemented by federal grants.

The dissenting members of the Council fear that a federal system of disability insurance would be subject to political pressures which would lead to excessive costs and unjustified expansion. Aside from the possibility of maladministration, there is considerable doubt as to whether disability is an insur-

able risk. Life insurance companies providing disability income benefits during the 1920's experienced large and increasing losses, culminating in the depression when disability rates reached a peak. Since that time, many of the companies have not offered disability protection; the remainder sell disability income insurance to carefully selected male applicants on a highly restricted basis and at high rates of premiums.

There are several reasons for predicting that the costs of federal disability insurance would exceed those of private insurance. Careful selection of risks is a prime factor in controlling the disability rate; yet a federal system must insure all persons within the scope of the program regardless of risk. Private insurance companies now provide disability coverage only to age 55; the proposed federal system would cover persons up to age 65. Almost all private companies limit disability coverage to men; in 1944, 40 per cent of the workers under Social Security were women. Disability rates during the depression rose less under ordinary insurance than under group insurance, which was issued on a wholesale basis without selection of risks.

A second major factor in determining the costs of disability insurance is the attitude toward admission of claims. As the dissent states, "In the federal system there would be strong pressure against, and little incentive for sound administration of claims." Unlike old age and survivors' insurance, determination of eligibility under a disability program would require considerable administrative discretion. Many unjustified claims would be made, especially during depressions when tax-free benefits would be more secure than wages and might be as attractive as net earnings after deduction of taxes, union dues, insurance contributions and the costs of transportation, meals and work clothes. This is especially true in the case of partial disability or failing efficiency, when the worker's earning power might be lower than the benefit payments based on prior earnings. On the administrative side, a liberal attitude toward admission of claims could be expected. Local administrators would probably be generous with the ample funds furnished from the old age and survivors' insurance reserve fund and, with the addition of a government contribution, from general revenues. Congressmen would be subject to pressure from constituents attempting to have their claims approved. The system would offer great opportunity for political manipulations; the expression of a liberal attitude toward claims by a political party would gain it the votes of large numbers of actual and potential beneficiaries and their families.

The third administrative control on costs is the review of admitted claims. Despite the specified periodic medical examinations, many persons would continue to receive benefits after total disability had ceased to exist. The line between ability and inability to work is not always clear; economic motivation may be the determining factor for the worker, and a careful physician would feel obligated to give the insured the benefit of any doubt. Needless to say, any system which reduces the incentive to rehabilitation and self support is undesirable from a social as well as a financial point of view.

The dissenting members of the Council suggest that the proposed disability insurance plan may be merely an entering wedge and that benefits and eligibility rules would soon be liberalized. Experience both here and abroad indicates that social insurance systems have a tendency to progressive expansion. The programs are generally popular with the public, especially if the employer and the government pay a large part of the costs. An administrative bureaucracy is built up which has a strong personal interest in the growth of the system. Successful operation is considered as a signal for an increase in coverage, benefits and costs, while defects are remedied by an extension of governmental regulation and control. Because of the strict eligibility rules and modest benefits proposed for the disability insurance program, costs would probably be relatively low at the outset, especially if the present high level of employment continues. This initial experience is likely to precipitate a liberalization all along the line, with a consequent increase in the claim rate and a decline in the recovery rate. Addition of a federal contribution to pay the rising costs would be accompanied by a tightening of federal control and growing opportunity for political exploitation of the system.

Although the 80th Congress failed to act on the recommendations of the Advisory Council, the issue of federal disability insurance is far from dead. Proposals for the expansion of the Social Security system and the inclusion of disability protection can be expected to appear during the next legislative session. Persons and organizations concerned with the problem should be prepared to support the principle of government provision for the permanently and totally disabled or to offer substitute plans. In thinking through their positions, they would do well to keep in mind the dangers inherent in any program, no matter how modest at the outset, which sets up a far flung federal bureaucracy with extensive discretionary powers.

Medical Motion Pictures

FILM REVIEWS

The following 16 mm., color, silent, motion pictures are a portion of the Sarnoff Surgical Motion Picture Library, Brooklyn. Produced and prepared by Jacob Sarnoff, M.D., Brooklyn. Procurable on rental from: United World Films, Inc., 445 Park Avenue, New York 22.

Osteotomy for Prognathism. 740 feet (2 reels), showing time twenty-one minutes (sound speed). Produced in 1946.

This film demonstrates the method of correcting protruding jaws by sectioning the ascending rami of the mandible. Part I shows the steps on models, cadavers and by animated drawings. Part II depicts the operative procedure on a patient. Certain deficiencies in the film should be noted. The titles are too infrequent, which leaves the average viewer, untrained in this type of surgery, at a loss to understand some of the steps. Mention is not made of possible hazards and pitfalls such as bony nonunion or injury to the facial nerve, nor does the film account for potential trauma to the inferior alveolar nerves and vessels by traction when the mandible is mobilized posteriorly into its new position. This film would be of interest chiefly to plastic surgeons, but would be of value from the educational standpoint to be shown at county medical societies, if someone experienced in this field were present for the purpose of discussion. The motion picture ends its second reel with the statement, "End of Part II." It is suggested that the term "Finis" be substituted so as not to leave the viewer in suspense. The photography is good.

Inguinal Hernia with a Review of the Anatomy and Surgery. 825 feet (2 reels), showing time twenty-three minutes (sound speed). Produced in 1944.

This film is designed to demonstrate anatomic features and surgical technic in inguinal hernia. A poor impression is immediately created by an erroneous definition in which a hernia is defined as "a protrusion of intestine." Throughout the scenes depicting operative technic, the skin around the incision is not draped, but is left exposed, thus breaking one of the prerequisites in a surgical teaching film. The surgeon is rough in his technic and goes through maneuvers intended to demonstrate something, but without making the point clear. Very heavy surgical gut is used entirely, usually with the strands doubled. Apposition of various structures in the repair is carelessly carried out.

Photography changes from color to black and white so frequently throughout the film that attention is distracted. Changes in scenes are also frequent, and aimless shifting of anatomic structures are so common that it is frequently difficult to discern what is being demonstrated, particularly since labels or descriptive text in the motion picture is almost totally lacking. The exposure in some scenes is good but in others so poor that structures are not well identified. The copies of drawings are overexposed. The lack of advance planning is evident in this motion picture.

Appendicitis. 490 feet (1 reel), showing time thirteen minutes (sound speed). Produced in 1943.

This film contains data on surgical pathology and operative technic. The author has obtained several good specimens illustrating various types of lesions, but information or descriptive material of the teaching type is not presented. During

the time when these specimens are photographed they are turned, shifted and "poked" so much that attention is distracted from the specimen itself.

The skin is not draped, but left exposed, thus breaking one of the prerequisites of a teaching film. Operative technic is careless; heavy surgical gut is used throughout, usually with the strands doubled. A sulfonamide powder is placed in the wound at the end of the operation, even though the appendix was not perforated or sufficiently inflamed to infect wound edges if they had been treated with average care. Since sulfonamide drugs are not being used much in that capacity during recent years, this procedure appears to date the film as not of recent production. Photography shifts from color to black and white. Most of the color photography is poor, the normal tissue color being preserved in comparatively a small portion of the film. Although considerable time must have elapsed during the period when the various specimens were collected, the rest of the film appears to have been made rapidly with little planning or thought given to the teaching value.

Milwaukee, Dec. 4. Final date for filing application is Nov. 27. Sec., Prof. W. H. Barber, Scott & Watson Sts., Ripon.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Histoplasmosis and Torulosis as Causes of Adrenal Insufficiency.—Rawson and his associates point out that certain fungus diseases may produce the syndrome of insufficiency of adrenal hormones by means of massive destruction of the adrenal glands. Despite their relative infrequency, histoplasmosis and torulosis should be kept in mind in any differential diagnosis of adrenal insufficiency. Literature contains 19 cases of involvement of the adrenals by *Histoplasma capsulatum*. One case is described in this paper. Twelve of the 19 cases showed some destruction of the adrenal parenchyma, and in 9 this destruction was of such magnitude that death was presumably due to adrenal insufficiency. Involvement of the adrenal by *Torula histolytica* has been noted far less frequently. Only 8 such cases have been reported. Only 2 of these showed any necrosis, and in only 1 (reported in this paper) was there necrosis extensive enough to produce the syndrome of adrenal insufficiency. Excessive weakness appears to be the earliest symptom of adrenal destruction caused by these two diseases.

Central Nervous System Involvement During Mumps.—Brown and his associates studied the incidence and characteristics of involvement of the central nervous system in 77 consecutive cases of mumps in which examinations of the spinal fluid were made. Pleocytosis with 10 or more cells per cubic millimeter was present in the spinal fluid of 26. Clinical manifestations of meningoencephalitis were recognized in 9 cases. These were mild in all but 1 patient. This patient suffered disabling residual damage to the nervous system which has persisted for three and one-half years.

Penicillin-Resistant Nonhemolytic Streptococcal Bacterial Endocarditis.—Clark and his associates report 9 cases of nonhemolytic streptococcal subacute bacterial endocarditis requiring treatment with from 1,000,000 to 12,000,000 units of penicillin daily. Eight of these patients recovered. The in vitro sensitivity of the causative organism to penicillin should, if possible, be determined before therapy is instituted. The initial daily dosage of penicillin should be based on these studies. Patients with sensitive organisms should receive at least 500,000 units per day. When the causative organism is moderately or markedly resistant, 1, 5, 10 or even 20 million units should constitute the daily dosage. Treatment should be continued for approximately four weeks. More prolonged therapy is usually unnecessary if adequate amounts of penicillin are used. Increased resistance of the organism to penicillin may develop under prolonged subcurative dosage. The daily penicillin dosage should be increased five to ten fold if the circulating blood is not promptly sterilized or if relapse occurs. There will be instances of unnecessarily intensive therapy, but arrest of the infection should more nearly approach 100 per cent. The drug may be effectively administered by continuous drip or intermittent intramuscular injections. The latter method is more simple. Large individual doses of crystalline penicillin can be given with minimal local discomfort. The use of anticoagulants is not indicated. Streptomycin may advantageously be used alone or simultaneously with penicillin in some cases of extremely resistant organisms.

Expulsion of Group A Hemolytic Streptococci by Sneezing, Coughing and Talking.—Hamburger and Robertson determined the numbers of beta and alpha streptococci discharged into the air of an experimental room during sneezing, coughing and talking in a series of 48 carriers of group A streptococci. By simultaneous employment of exposed blood agar plates placed on the floor and "broth bubbler" samplers whose intake was 3 feet (91.4 cm.) from the floor, streptococci expelled in large, rapidly falling droplets could be differentiated from those discharged as droplet nuclei which remained in the air for at least several minutes. The material dispersed into the air during a sneeze is chiefly saliva. Four dispersion patterns of beta hemolytic streptococci by sneezing were evident. In the most common, moderate numbers were expelled in large droplets which fell rapidly to the floor 1.5 feet (45.7 cm.) from the sneezer. In one of two less common patterns, small numbers of beta streptococci were sneezed as droplet nuclei. The material expelled during coughing apparently originates in the back of the throat or below the epiglottis and contains little if any saliva. Only one of 20 carriers coughed large numbers of beta streptococci into the air as droplet nuclei or in large droplets. Ninety-five per cent of the carriers coughed few or no streptococci. Practically no streptococci were recovered from the air of rooms while carriers counted out loud for five minutes. Although sneezing probably accounts for a certain

number of sporadic cases of the hemolytic streptococcal infection, it is not important in epidemics. The rare carriers whose sneezes heavily contaminate the air may be dangerous if they do not baffle the sneezes efficiently. Since the material atomized in a sneeze is saliva, these persons represent a type of dangerous carrier whose nose culture may be negative. Coughing, likewise, is important only in sporadic infections. Talking expels negligible numbers of hemolytic streptococci.

Treatment of Pelvic Endometriosis.—According to Schmitz and Towne endometriosis occurs in women at the height of their sex life and is a major cause of sterility. At their clinic it has been the aim to preserve ovarian function and to permit childbearing. A review of 130 patients treated with this intent shows that 57 were treated by surgical procedure. Ten required removal of both ovaries with or without the uterus. Forty-seven had one or both ovaries preserved, and 11 later conceived, giving birth to 13 infants. Roentgen therapy was employed in 29 cases, in 17 of which sufficient dosage to cause permanent menolysis was given. Twelve patients were treated with smaller dosage, causing a menolysis of three to eight months. In this group 2 conceived and delivered 3 infants. Roentgen therapy in this group proved satisfactory for secondary therapy when conservative surgical treatment had failed. Roentgen therapy of sufficient intensity to destroy ovarian function is indicated in cases in which endometrial tissue has invaded the bowel or bladder. It makes surgical resection with its increased risk unnecessary. Watchful expectancy or male hormone therapy is of value in young women with minimal disease and symptoms. It enables one to postpone more radical procedures to the years when such therapy is less costly.

Hyperthyroidism and Pregnancy.—Mussey and his associates state that of 30 pregnant women who received treatment for complicating hyperthyroidism at the Mayo Clinic, oral administration of strong solution of iodine U.S.P. (Lugol's solution) and thyroidectomy were used for hyperfunctioning adenomatous goiters, and Lugol's solution plus thyroidectomy, if needed, for exophthalmic goiter. Pregnancy did not seem to influence the course of hyperthyroidism in most cases. Likewise, proper treatment of the hyperthyroidism allowed the pregnancy to proceed normally. The authors are of the opinion that the standard treatment of hyperthyroidism by iodine and thyroidectomy can be carried out safely in the great majority of cases of hyperthyroidism complicating pregnancy. More information is needed about the effects of antithyroid drugs and of radioiodine before these methods can be used for treatment of hyperthyroidism in pregnant women.

Massive Dose of Penicillin in Chronic Asthma.—Sterling and his associates review observations on 15 patients with chronic asthma, in the majority of whom asthma had existed for over eight years. The patients had received general medical care and specific allergic treatment with pollen, dust and vaccine, when indicated, for at least six months to two years without marked improvement. Amorphous or crystalline penicillin, dissolved in isotonic sodium chloride solution, was injected intramuscularly every three hours. The initial dose was 10,000 units every three hours, increased daily if no local or constitutional reactions occurred to the penicillin. The second day 25,000 units was given every three hours. The next three days 50,000 units and then 100,000 units was given every three hours until a total dosage of 5,000,000 units or more had been reached. In 3 of the 15 cases, treatment was stopped because of severe reactions. The results were excellent in 3, good in 4 and fair in 1 of the patients who had completed the course of treatment with penicillin. The other 4 remained unimproved. The authors feel that one should not hesitate to use massive doses of penicillin in cases of intrinsic chronic bronchial asthma. The benefit to some patients is striking.

 Etiology of Optochiasmatic Arachnoiditis. W. L. Bruetsch.—p. 215.

Insulin Subshock in Psychoneuroses.—Sullivan states that treatment with insulin given by the intensive subshock technic is effective in producing not only symptomatic improvement but also remission, and perhaps some recoveries, in many of the psychotic patients seen in the Army. The intensive insulin subshock technic is effective with certain types of severe psychoneuroses. The author reviews the results obtained by himself and by other psychiatrists in Army hospitals. The majority of the patients treated had a diagnosis of "psychosis, unclassified, acute schizophrenic reaction." In most of these patients the disease showed considerable improvement or was in remission. Many of the patients had been psychotic three or four months before reaching the hospital from overseas. Despite such a long duration of symptoms, the majority still responded well. Intensive insulin subshock therapy consisting of adequate subshock reactions twice a day, seven days a week, for three weeks, should be used in treatment of all psychoses with schizophrenic symptoms. Intensive insulin subshock therapy should be used with all psychoneurotic states of the severe anxiety-tension type, psychoses with features of depression and psychoses of mixed type. When psychoses do not respond satisfactorily to intensive insulin subshock therapy a course of at least twelve electric shock treatments should be given (one treatment three times a week); this will increase the over-all rate of improvement and remission to 90 per cent. Intensive insulin subshock therapy is a relatively safe procedure and can be carried out in a group setup in which 20 to 30 patients are cared for by two nurses and five attendants. This personnel can be trained to recognize the signs and symptoms of reaction to insulin and the proper point at which to terminate the insulin subshock reaction by oral administration of sugared orange juice or intravenous injection of hypertonic dextrose solution. The proper point at which to terminate the subshock reaction is when the patient can barely be roused or shows evidence of impending convulsion.

 Appendicitis in Infancy: Report of Case. E. Kellert and A. Dumouchef.—p. 194.

Staphylococcal Meningitis.—According to Hoyne and Brown meningitis is uncommon during the first few weeks of life. Staphylococci are infrequent invaders of the meninges as evidenced by the fact that only 1 of 81 cases of meningitis in infants less than 2 weeks of age reported in the literature was of staphylococcal origin; it terminated fatally. Among all forms of meningitis in patients less than 2 weeks of age, there were only 7 recoveries. The authors report 1 case of meningitis due to Staphylococcus aureus in a 3 day old boy who was born of a primipara mother after an uneventful pregnancy. The infant was normal at birth. Delivery was by forceps, but there was no evidence of injury. The diagnosis was confirmed by positive cultures for hemolytic Staph. aureus from the spinal fluid and also from the blood. Sulfathiazole was given every four hours by mouth for fifteen days with a total dose of 15 Gm. During that period the highest blood level obtained for the drug was 4.0 mg. per hundred cubic centimeters. Sodium penicillin was administered by intramuscular route every two hours for two weeks with a total dose of 1,640,000 units. Both drugs were well tolerated. Twenty days after admission the infant was discharged as fully recovered. The method employed in the treatment of this infant emphasizes that neither intrathecal therapy nor frequent lumbar punctures are necessary for promoting recovery in meningitis.

Artificial Kidney in Uremia.—MacLean and his associates describe the technic of the use of the artificial kidney and discuss the effects of the dialysis on the patient. They report 3 patients in whom the artificial kidney was employed. The artificial kidney appears to be an effective method for removing waste products from the blood in uremia. Its clinical usefulness, in theory, is limited to those patients in whom the renal damage is temporary or reversible. It provides a means of saving such patients from death. It is well tolerated by the patient and apparently causes few harmful effects. The apparatus has a large field as an investigative tool. It should prove valuable in studying uremia because some "toxic" factor appears to be

removed from the blood and may be present in the filtrate. In addition it is a good method for studying the metabolism of various diffusible substances in the experimental animal and in human subjects.

Chronic Hepatitis.—According to Kilgour, the exact incidence of chronic hepatitis is most difficult to assess. Various estimates suggest that from 10 to 20 per cent of acute cases show activity for longer than four months, but experience in large epidemics indicates that this estimate is probably high. The author reports 4 patients who have had active hepatitis for thirty to thirty-six months. One apparently is recovering without clinical evidence of cirrhosis. The other 3 show clinical evidence and 1 histologic evidence of hepatic cirrhosis. Of the cases believed to be of cirrhosis one is apparently arrested, another improving, but the third presents the clinical picture of Hanot's cirrhosis; namely, chronic jaundice with enlargement of the liver and spleen but without ascites. The syndrome of chronic hepatitis may follow either epidemic infectious hepatitis or homologous serum hepatitis. It is particularly liable to follow cases of the acute disease which have been allowed to return to activity before recovery is complete or in patients who have been undernourished, affected with concurrent disease or subjected to trauma or surgical operations at the time of these factors. The actual cause of the prolongation of the hepatitis is unknown. Complete recovery occurs in the great majority, but in a small percentage the disease progresses to cirrhosis. It is possible that the progress may be arrested and complete functional recovery occur, even though cirrhosis has developed, but as yet insufficient time has elapsed to exclude relapse in the cases reported. The most effective treatment at present is prolonged rest and maintenance of optimum nutrition until all clinical and laboratory evidence of activity has disappeared.

Painful Back.—The 104 cases reviewed by Noble concerned men who applied to a Department of Veterans' Affairs for relief of painful back. The average age was 33. There were only 6 over 50 years. The intervertebral disk was involved in 42 cases. Postural strain, arthritis, spondylolisthesis, traumatic strain, spondylitis, tuberculosis, fibrositis and bone injury were some of the other etiologic classifications. Many cases of backache were improved by the lumbosacral brace. In particular, in patients who have had a laminectomy without subsequent fusion and who have residual symptoms referable to the back, the brace may afford considerable relief. Operations were performed on 26 of the 42 patients with disk lesions. In 5 of the 26 cases operated on, no disk protrusion was found. Sixteen of the 26 patients operated on were sufficiently restored to go back to work, but 14 of them could do only light work and only 2 could resume full duty. Of the 16 patients with disk lesions treated conservatively 11 could do light work and 4 could return to full duty; one could not be traced. Thus when a protruded intervertebral disk can be diagnosed operation may not necessarily restore the patient. A study of the nature of the trauma resulting in chronic pain in the back suggests that the best treatment may well be some form of prevention. The human species has a constitutional weakness at the lumbosacral junction. In order to compensate for this deficiency, postural training is required.

Human Relations and Industrial Health.—Line contends that present day circumstances in industry place an obligation on the medical profession, which it met during the war in the armed forces. In some respects the demand is more pressing, if only by virtue of the fact that whereas in the service there was a oneness of purpose, in industry there are two groups—workers and management. There is a great difficulty in communication between these two groups. Medicine has developed a high degree of skill in relieving the tensions of the maladjusted and alleviating the stress of individual situation-complexes by changes in the immediate social milieu. It has pointed up the significant fact that the work situation, the vocation, is all-important in determining personal mental health and has demonstrated the causal connection between interpersonal stress and labor management problems. The author directs attention to the influence of psychologic medicine in bringing about a revolution in the social sciences. It has demonstrated over and over again the dynamic sequence of authority, rejection,

hostility, guilt; and the consequent vicious circle. Difficulties of communication between industrial groups are being clarified by such researches as those of Elton Mayo, the Hawthorne researchers and the Chicago Committee of Industrial Relations. In industry medicine is able to assume a nonpartisan role in a worker-management society.

*Severe Systemic Sarcoidosis with Ascites and Splenomegaly. R. A. Mino, R. W. Frelick, A. I. Murphy Jr. and J. W. Hooker.—p. 65.

*Diverticula Arising at Pharyngoesophageal Junction: Discussion of Disease and Presentation of Unusual Case. R. A. Mino and A. I. Murphy Jr.—p. 75.

Severe Systemic Sarcoidosis.—Mino and his co-workers report 1 case of Boeck's sarcoid in a Negro woman aged 26 years with evidence of involvement of skin, lymph nodes, lungs, spleen, liver and pancreas and with presumptive involvement of heart, spinal cord and bone marrow. There was also massive enlargement of the liver with ascites and enormous enlargement of the spleen. Gratifying symptomatic relief of ascites, dyspnea and abdominal discomfort was afforded the patient by splenectomy and splenorenal venous anastomosis. The removed spleen measured 28.0 by 18.5 by 12.0 cm. and weighed 2,250 Gm., apparently the largest spleen recorded in Boeck's sarcoid. The diaphragmatic surface of its capsule showed scattered fibrinous adhesions and focal areas of hyalocapsulitis. The prognosis must remain guarded despite the obtained improvement in slowly progressive cases of Boeck's sarcoid similar to the one reported.

Diverticula at Pharyngoesophageal Junction.—Mino and Murphy report 1 case of an unusually large pharyngoesophageal diverticulum in a Negro aged 52 years who was admitted to the Memorial Hospital in Wilmington, Del. The patient's weight had gone from 130 pounds (59 Kg.) to 94 pounds (42.6 Kg.) in five weeks. A large ovoid mass in the right mediastinum was demonstrated on roentgenologic examination. It contained both air and fluid. The right lung was compressed by the diverticulum. The esophagoscope entered directly into the blind sac, the lowest limit of which was 28 cm. from the level of the upper incisors. No distal esophageal lumen could be seen. A Witzel type jejunostomy was done with the patient under local anesthesia. During the next three weeks the patient gained 26 pounds (11.8 Kg.) on jejunostomy feedings. Five weeks after admission, mobilization and exteriorization of the diverticulum was performed; the diverticulum was observed to extend into the mediastinum. Ten days later the old wound was reopened, the diverticulum freed and excised. Ten days after the second operation the patient was started on fluids by mouth, and soon afterward he was placed on a soft diet. Eleven weeks after admission he was discharged to his home, where he has continued on a full diet.

Frog Test for Pregnancy.—Robbins and Parker describe a new test for pregnancy utilizing the release of spermatozoa by the male *Rana pipiens* (common North American frog) on stimulation with mammalian chorionic gonadotropin. Its advantages are many. Small amounts (5 cc.) of whole urine can be

administered directly to each frog, making the test extremely simple. Reactions to positive urines develop sometimes within a half-hour and invariably within two hours, producing a test considerably faster than any previously described biologic test. The animals are widely available throughout the continental United States and as a result are extremely cheap; thus the cost of the test is most reasonable. To date a total of 122 samples of urine have been tested. Ten of these were obtained from normal girls having normal menses. The remaining 112 included 78 from women known to be pregnant and 34 from women with amenorrhea diagnosed not pregnant by the Aschheim-Zondek test or its Friedman modification. No false positive reactions were encountered. One false negative reaction occurred with a specimen of urine early in the period of gestation. The ease with which diagnosis of pregnancy can be established with this test makes possible its adoption in any laboratory. The rapidity that it affords makes of the test an emergency procedure of possible benefit in difficult diagnostic problems.

Gallbladder Gas Gangrene.—Brown and Milch cite reports which indicate that infection of the biliary tract with the organisms of gas gangrene occurs occasionally but is not frequent. Study of a consecutive series of 39 deaths following operations on the biliary tract at the Buffalo General Hospital showed that 6 apparently had infection with *Clostridium welchii*. Three of the patients undoubtedly died as a direct result of infection with *C. welchii*; in the other 3 cases, the infection may be considered as a major contributing cause of death. The authors report 1 of the 6 fatal cases and a history of a patient who survived. Infection with *C. welchii* is a considerable factor in mortality in surgery of the biliary tract, occurring more frequently than has been generally recognized. It can be suspected clinically, sometimes diagnosed roentgenologically, occasionally recognized at operation, and too frequently seen at necropsy. Since the necropsy findings may be confused with or obscured by postmortem change, blood cultures at the time of death are suggested. The occurrence of hematemesis in fatal cases, of "brown" vomitus in 2 others and of "black" stools in the patient who survived suggests that bloody vomitus may serve as a presumptive sign. The classical signs of gas gangrene appear later. The diagnosis of acute gaseous cholecystitis should be made by the roentgen shadow, and conservative treatment used, including penicillin and sulfonamide drugs. If the condition is encountered unexpectedly at operation, open packing of the wound seems wise. Routine use of gas gangrene antitoxin, roentgen therapy and sulfonamide drugs in connection with all

surgery of the biliary tract is unwarranted. The use of penicillin in all surgery of the biliary tract before, during and after operation might help prevent rekindling of the infection.

Prolapse of Gastric Mucosa.—Manning and Highsmith report 16 cases in which the clinical and roentgenologic findings were considered consistent with a diagnosis of prolapse of the gastric mucosa through the pylorus into the duodenum. No distinctive syndrome was found, but symptoms referable to the upper part of the gastrointestinal tract were present in all but 1 case. The characteristic roentgenologic finding consists of a circular, or irregularly circular, "mushroom" or "umbrella" filling defect in the base of the duodenal bulb, often associated with narrowing and elongation of the pyloric channel, and often with antral spasm and enlarged antral rugae. Uncomplicated cases of prolapsed gastric mucosa, especially when associated with hypertrophic gastritis, may be treated with a medical regimen. Surgical treatment, such as excision of the redundant mucous membrane and pyloroplasty, is indicated only in cases of pyloric obstruction, ulceration with recurrent hemorrhages, severe anemia due to chronic blood loss, polyp formation with malignant degeneration and suspected malignancy.

Contact Dermatitis Due to Streptomycin.—Shapiro and Carney report that at the State Sanatorium, Oakdale, Iowa, streptomycin has been used in the treatment of tuberculosis since February 1947. In the eight and one-half months prior to Nov. 15, 1947, approximately 40 nurses were engaged in the preparation and administration of streptomycin and the cleansing of syringes used for injection, without the recognized occurrence of dermatitis due to the antibiotic. After the change in the method of preparation necessitated by the increased amount of the product in each vial, 4 nurses out of 7 who engaged in its preparation had a contact dermatitis to streptomycin as indicated by a positive reaction to a patch test in each case. Even more striking is the fact that of the 7 nurses involved most of the preparation was done by 4, of whom 3 experienced the dermatitis. The authors point out that there is a possibility that contact sensitization will prevent future internal utilization of the antibiotic. Many of the nurses in tuberculosis sanatoriums are former patients. In the event of reactivation of their pulmonary tuberculosis, treatment with streptomycin might be indicated. Previous epidermal sensitization might result in the rapid establishment of a severe localized or generalized dermatitis contraindicating further use of the antibiotic. This probability renders them cooperative in attempts to prevent undue exposure to the drug. Such efforts consist in the use of rubber gloves and suitable technics of preparation and administration.

Serologic Changes in Primary Atypical Pneumonia.

—Marshburn demonstrates that of all the serologic changes occurring as a result of primary atypical pneumonia, the highest incidence of positive reaction follows the cold agglutination test. The value of the cold agglutination test in the ordinary cases of primary atypical pneumonia lies in the fact that it offers an objective means of confirming a diagnosis which can usually be made on the basis of the clinical picture, examination of sputum and roentgen findings. Significant titers of cold agglutinins are found consistently, and the level of the titer depends on the severity of the disease process. The majority of positive reactions to streptococcus MG agglutination tests occur in patients with significant cold agglutinin titers. A significant rise in virus-neutralizing antibodies occurs in the majority of cases when both agglutination reactions are positive. Therefore, positive reactions to the simpler tests for cold and indifferent streptococcus agglutinins might be provisionally considered as indicative of primary atypical pneumonia, when the history, physical findings and roentgen findings fit the picture, particularly if there is a rise in titer of these tests.

Rats Fed Army Combat Rations.—Sporn and Elvehjem fed the army combat rations K, C and 10 in 1 to young growing rats. Growth and reproduction over extended periods of time were the two criteria used in these experiments for evaluating the rations. Actually these rations were consumed for the most part by mature men in the field during relatively short intervals of time. When the K, C and 10 in 1 rations were fed to female rats, it was found that the survival rate of the young born to the females was low. The addition of liver to the K ration improved the percentage of survival of young born to females on this diet. The growth of male rats on these diets was suboptimum. The addition of the B vitamins and casein to the rations substantially improved growth in all cases. Normal growth was obtained when K and C rations were supplemented with casein and vitamins.

Monkeys and Army Combat Rations.—Sporn and his associates fed the army combat rations K, C and 10 in 1 ad libitum to young growing monkeys. Growth and hemopoiesis covering an extended period of time were the two criteria used in evaluating the several rations. The results of the experiments indicate that none of the combat rations tested could support growth in monkeys. The C ration could be substantially improved by the addition of a mixture of the water-soluble vitamins. The 10 in 1 ration produced normal growth in monkeys when supplemented with the vitamins plus raw whole milk. The K ration required the same supplements in order to support normal growth. The supplemented C and K rations could support a normal hemoglobin concentration. Normal growing monkeys on the supplemented K and 10 in 1 ration had suboptimum hemoglobin levels. For the growing monkey, K ration seems deficient in pyridoxine and folic acid, and possibly choline as well.

Protein Intake and Composition of Bone.—Estremera and Armstrong determined the effects on body weight and on the humeri produced by feeding to mature rats for thirty days equal amounts of essentially isocaloric diets containing 4.5, 9.0, 13.5 and 18.0 per cent protein as lactalbumin. It was found that a diet containing 4.5 per cent protein will not support

body weight of mature rats while diets containing 9.0, 13.5 and 18.0 per cent protein permit an increase in body weight in approximate proportion to the protein content. A diet containing 13.5 per cent protein supports a degree of skeletal constitution in mature rats equal to that of a diet containing 18.0 per cent protein. Diets containing 9.0 and 4.5 per cent protein are inadequate to support normal skeletal constitution in mature rats. Diets containing 9.0 and 4.5 per cent protein interfere with the growth in length of the humeri of rats which are near the end of the period of skeletal growth.

Dissolution of Urinary Calculi.—Keyser and his co-workers attempted to attack the organic matrix of 150 urinary calculi in vitro by treating them with ferments preliminary to irrigation with solvent solutions such as G solution (monohydrate citric acid, anhydrous magnesium oxide and anhydrous sodium carbonate in distilled water). Of the enzymes studied, 0.5 per cent urease is the most effective, with orthozyme, ficin proteinase and trypsin showing a comparable but lesser degree of activity. These enzymes act by a digestant action on the organic matrix (colloids) of the stone. This is partly dissolved and partly swollen so that the cementing substance which binds the crystalline matter together is loosened and renders the latter more susceptible to dissolution by crystalline solvents. Positive evidence is presented that such enzyme treatment in vitro accelerates and intensifies the action of G solution, especially on alkaline calculi. This treatment was given a clinical trial in 18 cases of urinary calculi and alkaline-encrusted cystitis. Irrigation was provided through three ureteral catheters, one inflow and two outflow catheters, which have been passed to the pelvis of the stone-containing kidney. The inflow catheter is connected to a Y tube which is attached to two containers.

a larger containing G solution and a smaller flask with the ferment solution. A Foley retention catheter conducts drainage from the bladder. There is presumptive evidence that the enzyme effect may likewise accelerate and intensify the effect of G solution and similar solvents in the dissolution of stones and calcareous material in the human being. In the problem of calculus dissolution the organic framework of stone is as important an object of attack as the crystalline matter.

Continuous Gastric Lavage in Treatment of Uremia.—Vermooten and Hare treated 7 patients between the ages of 55 and 86 years who had uremia associated with prostatism by continuous gastric lavage. When it was possible to introduce two nasal tubes into the patient's stomach, fluid was allowed to drip continuously into one tube while being automatically aspirated through the other. In the others ½ to 1 ounce of fluid was injected into the stomach through a Levine tube, which was then again immediately connected to a continuous suction apparatus. Fluid was injected into the stomach every ten minutes day and night. Continuous irrigation with about 10,000 cc. of fluid per twenty-four hours (about 150 drops per minute) yielded optimum results. Severe uremia was corrected within twenty-four hours after beginning continuous gastric lavage. The blood urea level dropped within the first seven hours and continued to drop so rapidly that the patients regained consciousness and were clinically well within forty-eight to seventy-two hours after the initiation of the treatment. The effect of continuous gastric lavage on 3 female patients between the ages of 23 and 28 years who had chronic nephritis with hypertension and uremia is also reported. Although as much as 1 Gm. or more of urea was removed in twenty-four hours by continuous gastric lavage, the azotemia in these cases persisted and became worse.

Food Sensitivity in 100 Asthmatic Children.—Hill studied 100 asthmatic patients and tested them by the scratch method. There were positive reactions in 218 scratch tests, but in only 44 or about a fifth was it definitely proved that the food could cause asthma. No symptoms were caused by 158 foods (72 per cent) to which tests showed cutaneous sensitivity. It is probably true that asthma would have been produced in some of these patients had a considerable amount of the food been ingested. Not uncommonly the degree of sensitivity to some of these foods, such as fish and nuts, is so high that as soon as any of the food touches the lips or enters the mouth the mucous membrane begins to swell and the food is immediately spat out or regurgitated before there has been any chance for it to be absorbed. If these cases are included, the number of foods producing asthma is increased from 44 to 60. About a fifth of positive reactions to scratch tests with foods in asthmatic children are of etiologic significance. The mother usually knows what food produces asthma, and has omitted it before cutaneous tests are done. Theoretically, any food can

cause asthma; practically, not many foods commonly do so. Fish, egg, walnuts, peanuts and chocolate are the most important. Wheat and milk can cause asthma in children, but do not often do so. Sensitivity to food, which should always be taken into consideration in asthmatic children, is of relatively little importance in comparison with sensitivity to pollen, other environmental allergens and infections of the upper respiratory tract.

Generalized Exfoliative Dermatitis Due to Penicillin.—Shaffer reports the case of a man, aged 27, in whom penicillin was employed in typical impetigo contagiosa of the skin. Generalized exfoliative dermatitis developed. Generalized exfoliative dermatitis is a complication to be feared and should not be risked by the local application of penicillin ointment to an innocuous skin lesion. In the case reported continuation of intramuscular penicillin after the occurrence of the generalized rash might have caused a fatality. The occurrence of localized exfoliative dermatitis in other cases has illustrated the dangers of local penicillin. Penicillin ointment is contraindicated in the treatment of cutaneous lesions not only because of the reactions dangerous to life that may occur during the treatment of an innocuous condition but also because systemic sensitization may prevent later parenteral use of penicillin when it is needed to combat a severe systemic infection.

Acute Laryngotracheobronchitis.—According to Everhart acute laryngotracheobronchitis is predominantly a disease of infancy and early childhood. The author and others saw numerous cases of this type in a town in Texas during the winter of 1946 to 1947. About two thirds of the 67 patients treated by the author and another physician were cared for in their homes; the others were hospitalized. Throat cultures were taken and Schick tests were done on patients not recently immunized against diphtheria. None of the cases with laryngeal and obstructive symptoms reviewed here proved to be diphtheritic in origin. Sulfadiazine was given to each patient, and some received from 150,000 to 300,000 units of penicillin in oil and wax. Chemotherapy and rest in a warm, moist atmosphere play an important part not only in reducing the number requiring tracheotomy, but also in shortening the postoperative period. Tracheotomy, to be effective, must be done before the patient becomes exhausted. Four of the patients reviewed here required tracheotomy, and all recovered.

Immediate Attention to Postpartum Cervix.—Tollefson says that since 1936 it has been the practice at his hospital to inspect all cervixes after the completion of the third stage. All lacerations of 1 cm. or more were repaired if there were no contraindications. Subsequent examination proved that immediate care of these cervixes established the normal contour of the structure with a complete covering of squamous epithelium and no evidence of eversion or erosion. The edges were trimmed and sutures were placed about 0.75 cm. apart, including the entire musculature down to the mucosa. Of 1,269 women delivered, 380 of whom were primiparas, 672 underwent cervical repairs. Excellent, good or fair results were obtained in all but about 4 per cent. This figure compares favorably with over 36 per cent of poor results in the 597 women who did not undergo repair. All cervixes should be inspected after delivery of the placenta and all injuries greater than 1 cm. should be repaired. When there is considerable thinning of the angles with minimal laceration, the edges should be trimmed and sutured in order to reestablish the normal contour of the cervix and prevent eversion, erosion and cervicitis. Repair of the cervix should not be attempted when there is decided relaxation of the uterus, when there has been a recent infection and when prolongation of the anesthetic would be dangerous. Immediate care of the cervix has an important place in the prophylaxis of cancer of the cervix.

Treatment of Carcinoma of Cervix. R. S. Cron.—p. 480.

Anesthesia and Hepatic Function.—Pohle made a number of tests of hepatic function before and at intervals after operation in 154 patients. The patients were anesthetized with one of six agents as follows: chloroform, ether, cyclopropane, dibucaine hydrochloride (spinal), "pentothal sodium" or tribromoethanol. The duration of anesthesia was long and the operative procedures extensive. The majority of the patients were not well nourished. Impairment of hepatic function was detected after operation in about 50 per cent of the cases irrespective of which of the six anesthetics had been administered. The alterations in function were transitory and were rarely suspected clinically. Many factors besides the anesthetic agent contribute to the decrease in hepatic function frequently observed postoperatively. The importance of the nutritional state and the avoidance of oxygen lack are emphasized. The present observations suggest that the deleterious effects of chloroform on the liver have been overemphasized in the past. However, the adverse cardiac effects which frequently occur do not warrant a general revival of the use of this agent in clinical practice.

Hepatic Lesion Due to Carbon Tetrachloride.—Andrews and Macgregair say that in the course of experiments designed to elucidate the pathogenesis of centrilobular changes in malaria, the effect on the liver of administering carbon tetrachloride, chloroform and phenylhydrazine was investigated. Both carbon tetrachloride and chloroform, if given in sufficient dosage, lead to centrilobular necrosis and degeneration. The authors provide evidence that the lesion is due, at least in part, to anoxia of the central region of the liver lobules, secondary to obstruction of the blood flow through the sinusoids. This obstruction arises from swelling of the parenchymal cells, which leads to a diminished vascular bed within the liver. The majority of the experiments were made on albino rats. The authors describe a method of outlining the hepatic sinusoids with india ink.

New Sulfonamide Drug in Chemotherapy of Cholera.

—According to Bhatnagar and his associates of Bombay the new compound "6257," which is a condensation product of sulfathiazole and formaldehyde, shows great bactericidal and growth-inhibiting action against *Vibrio cholerae* in in vitro tests. When administered parenterally to mice it gives 100 per cent protection against septicemia resulting from intraperitoneal cholera infection. It is not so successful when given by mouth. This is due to deficient blood concentration of the drug. In the course of an epidemic in an endemic area, patients were treated in their homes with this drug. In the absence of any adjuvant treatment, the survival rate compared favorably with that obtained by the usual therapeutic methods. Although patients have usually recovered at the end of seventy-two hours, a schedule of treatment extending over seven days is advised because of the persistence of cholera vibrios in the stools. In the present series the excreta were free from vibrios on the sixth day. The two outstanding properties of "6257" that are in sharp contrast to those of other sulfonamide derivatives are the absence of toxicity within the zone of therapeutic action, its slow absorption from a subcutaneous "depot" and equally slow excretion from the system, so that blood concentration can be maintained at a higher level for a longer period of time. If future experience shows that the therapeutic value of "6257" and that of other similarly prepared compounds possessing these two qualities extends over a wider field of pathogenetically important bacterial species, it might be that the sulfonamide derivatives would regain their place of priority in clinical therapy. This would be a welcome reversion from the point of view of production as well as economy.

Streptomycin in Tuberculous Meningitis.—Marshall and his associates say that in September 1946 the Medical Research Council appointed a committee to direct clinical trials of streptomycin in the treatment of tuberculosis. This report is concerned with the results in tuberculous meningitis. The centers kept uniform records and followed general recommendations regarding dosage. The general results reported here refer to a total of 105 proved cases. All the cases were proved by culture, by guinea pig inoculation or by postmortem examination. A more detailed analysis is concerned with 92 of the cases. Of the 105 patients 67 have died, and of the 92 patients 61 have died. Of the 33 children under 3 years, 27 died; of the 72 older children and adults, 40 died. Of the patients admitted at an early stage of the disease, 42 per cent were making good progress, compared with 26 per cent of those at a medium stage and 7 per cent of those at an advanced stage on admission. This indicates the great importance of early diagnosis. Of the patients who received streptomycin only intramuscularly, 11 per cent made good progress, compared with 35 per cent of those receiving streptomycin by both intramuscular and intrathecal routes. In patients who ultimately fared badly, tubercle bacilli were isolated from the cerebrospinal fluid much more frequently during the first three weeks than in patients who made good progress. Strains isolated from 22 patients between the twenty-ninth and the one hundred and thirty-sixth day of treatment were tested for sensitivity; only 3 of these were resistant to streptomycin.

Intensified Electrical Convulsion Therapy.—Page and Russell studied the effect of increased voltage and duration. The voltage was gradually increased from the minimum of 100 volts necessary to produce a major convulsion to a fixed standard of 150 volts. The duration was similarly increased from 0.3 second to a standard of 1 second. The effect of repeated electrical shocks administered during the convulsive phase was investigated. Ultimately a standard of 150 volts for 1 second followed by five shocks during the primary convulsion was reached, since it was noted that, once a major convulsion had been induced, no increase in intensity of the convulsion resulted from the extra shocks. Treatment is given daily and never less than two hours after a meal. The few patients who show apprehension or are known to be restless after treatment are given sedation. Daily treatment is stopped as soon as there is a remission or pronounced confusion. It is seldom necessary to reach confusion, because a remission usually takes place after the first few treatments. Amnesia resulting from the treatment can be ignored, and the course continued. Memory always returns within a few days. The risk of fracture seems to be less with the new technic than with the old. More than 300 patients have received treatment by the new technic and more than 1,500 individual treatments have been given without fracture or dislocation.

*Primary Atypical Pneumonia: Report of 112 Cases with Positive Cold Agglutination Reaction. G. Laurell.—p. 299.

Primary Atypical Pneumonia.—Laurell reviews observations on patients with suspected primary atypical pneumonia whose blood samples were examined for cold agglutinins. The reaction was positive in 112 cases and only these cases were included in the present investigation. This does not mean, however, that clinically typical cases in which the reaction was negative could not have been primary atypical pneumonia. The reaction to the cold agglutination test was considered positive when, from having been negative in serum taken during the acute phase of the disease, it was positive in the convalescent stage with a titer of at least $\frac{1}{8}$ to $\frac{1}{16}$. The same was the case if the titer increased during the course of the disease from $\frac{1}{4}$ to $\frac{1}{16}$. A single titer value of $\frac{1}{16}$ when obtained during the convalescent phase was also regarded as positive. The author reviews clinical, laboratory and roentgenologic observations and describes 2 typical cases. The cases of primary atypical pneumonia observed in Sweden show essentially the same features as those described by Anglo-American investigators. Contrary to the observations made by American investigators, even cold agglutination as low as $\frac{1}{16}$ had diagnostic value. Treatment with sulfonamide compounds and penicillin does not seem to have had a noticeable effect on the course of the disease.

*Treatment of Acute Nephritis. Y. Y. Shpirt.—p. 107.

Living and Dead Cells Under Ultraviolet Microscope. L. P. Larionov and E. M. Brumberg.—p. 111.

Treatment of Acute Nephritis.—According to Shpirt acute nephritis may be divided into three stages. In the initial phase of less than two weeks' duration, the predominant factor is arteriolar and capillary hypertension that causes cardiovascular deficiency and glomerular involvement. In the second stage, lasting from two to twelve weeks, inflammation of the glomeruli with other changes is predominant. Hypertension is still present, but heart failure and edema are often not in evidence. In the third stage there is advanced involvement of the glomerular apparatus. The reappearance of arteriolar hypertension at this stage should be considered as secondary to the inflammation in the kidneys. To reduce the hypertension of the arteriolo-capillary system that was caused by a disturbed neuroregulatory mechanism, the authors used one bilateral paranephric block. Fifty cubic centimeters of a 1 per cent solution of magnesium sulfate was injected on each side. Seventeen of 20 patients with stage 1 nephritis responded to paranephric block. All clinical signs of the disease disappeared in ten days. In the second stage of the disease, block reduced the high blood pressure and edema in ten days, but the urine did not return to normal. In the third stage of acute nephritis, block was not effective, sometimes causing increase of albuminuria and hematuria. In nephrosis, as well as in nutritional edema, block aggravated the condition.

*New Method for Quantitative Determination of Chorionic Hormone. N. de Castro Barbosa.—p. 115.

Method for Determination of Chorionic Hormone.—De Castro Barbosa found that in the Galli-Mainini test for pregnancy, liberation of spermatozoa from the toad's testicle and their elimination in the toad's urine take place only when the hormone in the injected urine is in a certain concentration. The minimal concentration capable of stimulating liberation of

spermatozoa constitutes the toad's chorionic unit (Bufo unit), which is equivalent to 10 international chorionic units. Liberation of spermatozoa occurs as soon as the hormone reaches the testicle. Spermatozoa appear in toad's urine forty to fifty minutes after the injection and not before, regardless of the concentration of hormone in the injected urine. The greater the concentration of hormone in the injected urine, the greater the number of spermatozoa in the urine. The Galli-Mainini test for pregnancy can be used for quantitative determination of chorionic hormone in urine or in the pharmacologic assay for chorionic hormone in drugs.

*Analysis of 100 Consecutive Cases of Acute Myocardial Infarct: Preliminary Report with Discussion of Use of Anticoagulants. S. Zajarías and L. Méndez.—p. 278.

Acute Myocardial Infarct.—Zajarías and Méndez analyzed 100 consecutive cases of acute myocardial infarction observed at the National Institute of Cardiology of Mexico. The anticoagulant treatment was not administered to patients in this group. Mortality and morbidity of this group were lower than those reported by Nay and Barnes in a group of 100 patients who did not have anticoagulant treatment, and lower than those observed by Parker and Barker in 50 patients who were given anticoagulant treatment. The authors feel that anticoagulant treatment should be resorted to only in cases showing a certain degree of thrombophilia.

*Diseases Associated with Thyrotoxicosis. O. Selvaag.—p. 375.
Osteoporosis with Collapse of Spinal Column After Prolonged Administration of Thyroid Hormone. E. D. Bartels.—p. 382.

Prolonged Treatment with Methylthiouracil in Thyrotoxicosis.—The treatment was started in Bispebjerg Hospital and was continued in ambulant patients under control. Kjerulf-Jensen and Meulengracht state that the 170 patients on transfer to ambulant treatment were as a rule able to work at once or soon, except in cases in which age or other than thyrotoxic disorder interfered. The duration of the treatment varied from five to thirty-seven months. On a follow-up 38 patients were still under treatment, 20 had completed the treatment less than three months previously; 101 patients were observed from three to thirty-four months after the treatment, an average of seventeen months. All thyrotoxic symptoms had disappeared or regressed. In most cases there was a gradual decrease in the size of the goiter after the treatment, and in some cases complete disappearance. Adenomatous goiter present before the thyrotoxicosis is the most likely to persist, but has been known to decrease in size after treatment. In 10 cases there was a recurrence after a symptom-free period of nine to thirty months. Later recurrences may be expected. Recurrence calls for another treatment with methylthiouracil.

Prolonged Treatment with Methylthiouracil in Hyperthyreosis.—Frisk says that since 1944 in 160 cases hyperthyreosis has been treated with methylthiouracil, in some cases with similar substances. Thyroidectomy was done in 14 cases, and for various reasons the treatment was discontinued in another 12 cases. In 73 of the remaining cases the treatment was completed in three to thirty-six months. In 20 cases recurrence led to repeated treatment, now ended in 8 cases. Sixty-one patients, 32 observed for over a year and 23 for over a year and a half, continue to be without symptoms after withdrawal of the drug. Previously untreated patients with enlargement of the thyroid and patients on whom thyroidectomy has been done respond most rapidly to the treatment and have the best chance of permanent remission. Hyperthyreosis with considerable disturbance of the thyroid, toxic adenoma and intrathoracic goiter

should be treated operatively. Treatment with thiouracil derivatives for two weeks is advised; the reaction of the patient and his cooperation can be observed during this time and the decision as to treatment made.

Diseases Associated with Thyrotoxicosis.—Hypertension was present in 51 of Selvaag's 392 cases of thyrotoxicosis; coronary thrombosis in 2; valvular heart defect in 7; simple anemia in 96; disorders of the respiratory organs in 11, of the digestive tract in 25, of the urogenital tract in 21, in other endocrine organs in 19; polyarthritis in 9 cases; humeroscapular peri-arthritis also in 9; rheumatic fever in 2, and nervous disorders in 5. Combined diabetes and thyrotoxicosis were encountered in 8 cases.

*Sciatica With Intermittent Claudication Due to Enteroptosis. J. M. Obarrío.—p. 387.

Sciatica of Intermittent Claudication Type.—The author reports 3 women between the ages of 33 and 42 with subjective disturbances of sensation in the distribution of the greater sciatic nerve, and paresthesia, which disappeared in two patients and diminished in one when the patients were in the horizontal position and reappeared when they were in any other posture or when they walked. This type of sciatica is a form of neuritis of the greater sciatic nerve with intermittent claudication which can be unilateral or bilateral and which may be complicated by neuritis of other nerves originating in the lumbar or sacral plexuses. The main symptoms are pain and paresthesia. In some cases there is hyposthesia or hyperesthesia. The motor function, tone and nutrition of the muscles supplied by the sciatic nerve are frequently diminished. The neurologic signs correspond to the distribution of the greater sciatic nerve. The condition is due to enteroptosis with consequent compression of the sacral plexus in the pelvis by intestinal loops. The prognosis is favorable. The treatment consists of the correction of enteroptosis.

Osteotomy in Pseudarthrosis of Neck of Femur. G. Menegaux and B. Lascoux.—p. 338.

Syndrome of Mauriac: Glycogenosis and Hepatomegaly. A. Hanns.—p. 339.

Myocardial Infarct Following Stellectomy.—Danielopolu stresses that when Lonnescio in 1922 reported his first case of angina pectoris in which stellectomy had been done, he at once objected to the interruption of the sympathetic fibers of the myocardium and of the coronary vessels, with their vasodilator effect, in a disorder in which the myocardium is frequently impaired and in which coronary spasm is one of the chief factors. That his warning was justified is proved by the fact that acute cardiac insufficiency, sudden death and myocardial infarct may follow stellectomy. In view of the fact that this operation has no other effect than the suppression of the pain in the chest and that it fails to prevent the attacks, which may prove fatal, he reemphasizes his warnings against any operation that suppresses the dilator system of the coronary circulation.

Bloodless Opening of a Tuberculous Cavity.—Maurer describes a method of bloodless opening of a tuberculous cavity by which the occurrence of a phlegmon and of disadvantages associated with Monaldi's suction drainage may be avoided.

A cavity is punctured through the thoracic wall with a trocar consisting of a trocar point with steel wire, a Laminaria hollow peg which covers the wire, and a metal cap with central boring, a regulator screw and two side wings serving as handle of the instrument. The exchangeable Laminaria peg is the main feature of the technic. A set of pegs are employed 12 cm. in length but of diameters which increase 1 mm. each from 6 to 13 mm. The peg of smallest diameter is used first and is left in the puncture canal for twenty-four hours; it swells and is then removed to be replaced by a cavity catheter around which the puncture canal closes, thus preventing any infection. The catheter is replaced by a peg with a wider diameter. By several repetitions of this procedure a gradual dilatation of the granulation canal is obtained. The cavity contents are drawn off every morning. The closure of the draining bronchus occurs either spontaneously or by cauterization with the aid of the thoracoscope. Streptomycin therapy is instituted after the swollen Laminaria peg has been replaced for the last time by a 18 mm. cavity catheter which remains in the drainage canal for three days. A strip of gauze immersed in a streptomycin solution is introduced into the cavity; after that 0.1 Gm. of streptomycin in 12 cc. of an isotonic sodium chloride solution—1 cc. every two hours for twenty-four hours—is dropped on the gauze, which acts as a wick within the cavity. Local application of streptomycin may be combined with intramuscular injections of the drug. The tamponade of the cavity is repeated every two to four days. The method is indicated in cavernous phthisis no longer amenable to medical treatment or to surgical intervention because of the size and the location of the cavity, in respiratory insufficiency or in the presence of myocardial lesions or of severe extrapleural foci such as intestinal tuberculosis.

*Evaluation of Pleural Involvement in Course of Tuberculosis in Cases with Subsequent Skeletal Tuberculosis. A. Ravelli.—p. 271.

Penicillin in Treatment of Mastitis with Abscess Formation. A. Kotek.—p. 274.

*Flies as Carriers of Poliomyelitis Virus. F. Puntigam.—p. 276.

Pleurisy and Tuberculosis.—Ravelli stresses that tuberculous pleurisy appears as an early manifestation of tuberculosis and must be given the same serious consideration as the early tuberculous infiltration of lung. Pulmonary tuberculosis develops in 20 to 30 per cent of patients within two years of the appearance of tuberculous pleurisy. Tuberculous dissemination into the systemic circulation, particularly the skeletal system, is frequent. The author presents several case histories which demonstrate that tuberculous pleurisy may be followed within the year by a skeletal tuberculosis. A skeletal lesion may be recognized as tuberculous when the previous history reveals an attack of tuberculous pleurisy or when roentgenologic examination reveals traces of an earlier pleurisy. Thorough examination and sufficiently prolonged treatment and care of patients with tuberculous pleurisy may prevent the development of skeletal dissemination.

Flies as Carriers of Poliomyelitis Virus.—Puntigam says that the Canton Wallis and the city of Lucerne have employed a systematic eradication of flies by means of spraying with 1 per cent solution of DDT (4,4'-dichlorodiphenyltrichloroethane) for the last two years. Comparison of the morbidity figures for poliomyelitis before and during the time that flies were eradicated with DDT revealed that this measure had no influence on the course of outbreaks of the disease. The author points out that these investigations corroborate the opinions of Fanconi, who does not regard flies as the necessary intermediate hosts of poliomyelitis. It is possible that flies occasionally carry poliomyelitis virus as they do typhoid bacilli. For this reason it is advisable to combat flies in the sick room and its immediate surroundings and also to disinfect the excreta of patients with poliomyelitis.

Book Notices

Compulsory Health Insurance. By Elizabeth W. Wilson. Studies in Individual and Collective Security No. 3. Paper. Price, \$1. Pp. 138, with illustrations. National Industrial Conference Board, Inc., 247 Park Ave., New York 17, 1947.

The book is a cross between an actuarial and an economic treatise on the subject of sickness insurance. Miss Wilson is a student of statistics and uses charts and tables liberally in developing her arguments against compulsory health insurance; nor does she rely entirely on her own knowledge but draws from numerous sources in piecing together over five hundred quotations and references. The government's interest in health insurance is traced from the passage of Britain's National Health Insurance Act in 1911 to the introduction of the Wagner-Murray-Dingell bills. The Wagner-Murray-Dingell bills, especially the bill introduced in 1945, are exposed in their true light. The author considers carefully the problems of administration, particularly those in regard to malingering, adequate benefits, cooperation of personnel, methods of paying physicians and government interference. "Medical adequacy" and "economic feasibility" are considered important enough to require separate chapters. Completing the book is a long list of pros and cons on the subject, arranged in parallel columns to provide a quick résumé of the arguments on both sides of the subject. "Compulsory Health Insurance" is a refreshing book. Every medical society, medical school, hospital, and college library should have a copy on file.

Psychopathology and Education of the Brain-Injured Child. By Alfred A. Strauss, President, Cove Schools for Brain-Injured Children, Racine, Wis., and Laura E. Lehtinen, Educational Director, Cove Schools for Brain-Injured Children. Cloth. Price, \$5. Pp. 286, with 45 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16, 1947.

This book presents the results of intensive psychologic and educational research over twenty years. It is a major contribution to the understanding and management of the child whose intellectual, personality and behavioral deficiencies result from organic damage to the brain. It is concerned primarily with children who do not have severe cerebral palsy or other motor involvement—a group which has been more neglected, probably, than any other type of mentally defective or neurologically afflicted child.

The first section of the book deals with the psychopathology of the child with an injured brain. After chapters on a historical review of the problems and anatomic considerations come the three most significant chapters of this section, describing the perceptual, conceptual and behavioral disorders of children with organic brain disease. There is a description of a number of ingenious psychologic tests for evaluating the kind and degree of disturbance of perception and concept formation. These tests are still qualitative rather than quantitative, but further research may lead eventually to their refinement on a par with the well established standardized psychometric technics. Some of the tests described are entirely original; others are adaptations or modifications of technics used in the more widely explored field of the psychopathology of the brain damaged adult. The research on behavior disorders is less satisfying; although there is a fairly clear picture of the behavior disturbances which result from brain injury, there seems to be no way of distinguishing behavior patterns resulting from such injury—such as lack of inhibition, hyperactivity, impulsive action and irritability—from similar patterns resulting from schizophrenia, neurosis or other emotional disorders.

The section on the education of the child with an organic involvement of the brain is rich in detailed descriptions of novel technics and devices for teaching this type of child. General educational procedures—such as the elimination of distracting stimuli from the outside, within the schoolroom and from study materials or the provision of manipulative devices—are geared to the specific defect. Illustrated and carefully described materials and methods are presented for the major educational areas of arithmetic, reading and writing. The variety and nature of the devices, facilities and technics described, the need for adaptations for each case and the slowness of the educative process in these children necessitate a special, and expensive,

school set-up for the child with an injured brain. However, teachers in institutions for the feeble minded, public school classes for the mentally handicapped and even in schools for normal children will find much that can be useful to them.

Clinical child psychologists and workers in the field of special education are the groups to whom this volume will be most directly and repeatedly useful. However, it is to be highly recommended, also, to neurologists, psychiatrists, pediatricians and all other physicians who have contact with disturbed or retarded children.

Techniques de laboratoire: Chimie physique, chimie biologique, chimie clinique. Par M. Abribat et al. Secrétaire de la rédaction: J. Lolsieur, chef de service à l'Institut Pasteur. Préface de M. J. Tréfouel, directeur de l'Institut Pasteur. Paper. Price, 1600 francs. Pp. 907, with 169 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris, 6^e, 1947.

This book attempts to correlate physical chemistry, biologic chemistry, and clinical chemistry. Its sequence is well carried out, beginning with general considerations of methods of examination. The first chapter discusses the various implements and solutions in titration fluids. The methods of measuring viscosity are explained.

There is a chapter by Latarjet, of the Institute of Radium of the Pasteur Institute of Paris, on radiations in biochemical technics. This is an unusual chapter and one of great importance. There is another chapter on photometric determinations of various absorbents.

In the third part on biological chemistry there is a complete and exhaustive description of microchemistry of the various metals.

The isolation, purification and crystallization of proteins is fully described by J. J. Perez, Chief of the Laboratory of the Pasteur Institute. There is a complete chapter on the potentiometer titration of proteins and also a complete story of certain amino acids. The nucleoproteins are fully discussed, as are lipids and glucides. An unusual chapter is that dealing with quantitative immunochemistry and its use in immunology and chemistry. The estimation of the various mineral elements in plasma is considered thoroughly.

The latter part of the book, devoted to clinical chemistry, will be found most interesting to clinical pathologists. There are taken up urinary acidity and the nitrogenous constituents of normal urine, as well as the fixed mineral elements of urine. Urinary albumin is the subject of a special chapter, and it is well described. There is a special chapter on the microscopic examination of urinary sediments. Another chapter is devoted to the pathologic variations of spinal fluid and of fecal material. The amount of sulfonamides in blood, urine, spinal fluid, and tissue is thoroughly described, as is the estimation of vitamins and hormones in biological fluids.

The function of the liver is discussed in a chapter entitled "Functional Activity of the Liver According to Blood and Urine Analyses." The functional activity of the kidneys is also considered fully.

All together, this is an excellent reference book for any laboratory. The latter portion of the book is especially interesting to the clinical pathologist.

A Text-Book of Pathology: An Introduction to Medicine. By William Boyd, M.D., M.R.C.P., F.R.C.P., Professor of Pathology and Bacteriology of the University of Toronto, Toronto. Fifth edition. Cloth. Price, \$10. Pp. 1049, with 530 illustrations. Lea & Febiger, 600 S. Washington Square, Philadelphia 6, 1947.

The first edition of Boyd's "A Textbook of Pathology" appeared in 1932 and the new fifth edition in 1947. The average of one new edition each three years is an indication of the popularity of this book. The new edition maintains the same high quality of clarity and readability and the same scientific standards that characterized the preceding editions. In his preface to the first edition the author stated that the volume was "intended for students of pathology, whether undergraduate or postgraduate, and not for the pathologist and professional laboratory worker. . . . The object of the student should be to gain a grasp of the fundamental principles underlying the subject." Dr. Boyd has, therefore, presented the general principles of pathology with clearness and force and has pointed out the application of these principles

to the practice of medicine. "Pathology in relation to the living patient is the motif of this book."

The fifth edition consists of 1,049 pages, of which 351 are devoted to general pathology, 667 to special pathology and 29 to the index. It has been extensively revised, some parts have been rewritten and new material has been added. The author mentions 30 new sections that have been added. Among these are: lipotropic factors in relation to diseases of the liver, dermatofibroma, sclerosing hemangioma, myocardial infarction without coronary occlusion, Loefler's pneumonia, intestinal lipodystrophy, alloxan diabetes, renal anoxia, interstitial cell tumors of the testis, primary splenic neutropenia and fibrous dysplasia of bone. New material pertaining to twelve subjects has been added; among them are cystic fibrosis of the pancreas, folic acid in relation to macrocytic anemia, the pathogenesis of poliomyelitis, hemochromatosis, burns, Dock's observations on the structure of the coronary arteries and allergy in the production of lobar pneumonia. Seven sections have been entirely rewritten: carcinogenesis in its relation to enzymes and viruses, silicosis and anthracosis, necrosis and cirrhosis of the liver, Cushing's syndrome, the Rh factor in congenital hemolytic disease, ankylosing spondylitis and Volkmann's contracture. A section on allergy, omitted from the preceding edition, has been rewritten and reinserted.

The volume contains 500 illustrations, which, in general, are excellent, and 30 colored plates, illustrating both gross and microscopic lesions. Dr. Boyd's manner of presenting the general principles of pathology is positive and at times, perhaps, dogmatic, but his opinions are generally sound in the light of present knowledge. Pathologists, even if they found nothing new in the book, could learn much from the method of presenting a difficult subject. The practitioners of medicine or surgery will find it useful if they desire "to indulge in the periodic brain dusting recommended by Osler." This book is well printed on paper that is only slightly glossy and can be read without undue eye strain.

Glomerular Nephritis: Diagnosis and Treatment. By Thomas Addis, M.D., F.R.C.P. Cloth. Price, \$8. Pp. 338, with 59 illustrations. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

For four decades Thomas Addis has been a path-finding investigator of the kidney in health and disease. His many studies have significantly advanced understanding of the function and architecture of the pathologic kidney and the clinical aspects of renal disease. This lifework has now culminated in a monograph: "Glomerular Nephritis: Diagnosis and Treatment." Actually, the book contains much more than the title suggests. It serves as a medium for presenting not only Addis' often unorthodox views on Bright's disease, but also his basic philosophy of medical practice at a time when accumulation of knowledge in diverse fields has rendered it more difficult for the individual physician to insure his patient the maximum available help. The book starts with a chapter on relatively simple laboratory methods developed by Addis, which require few facilities and little technical help but nevertheless are sufficiently accurate for guidance of treatment. A brief section on dietetic principles follows. Means for inferring the nature and extent of a renal lesion are elucidated in detail. After an interesting development of the basic principles of classification of disease in general and of renal maladies in particular, the differential diagnosis and clinical picture of glomerular nephritis are covered in extenso. Finally, the treatment of glomerular nephritis is discussed, with a useful appendix on quantitative dietetics for patients.

Addis' monograph is the antithesis of a textbook. It is largely a presentation of his own observations and experiments—many not previously published—with little discussion of literature. Addis has decided views on many controversial problems and presents detailed evidence in support of his opinions. Particularly documented are the descriptions of his many years of experimentation with partial ablation of the kidneys in rats and the effects of various diets on survival. Largely on the basis of these experiments, Addis feels that impairment of renal function in glomerular nephritis may be retarded by diets as low in protein as is consistent with good nutrition. He holds that greater "osmotic work" by the tubular cells when more urea is excreted accelerates failure of the

kidney and that a low protein diet "rests" the kidney. Addis thus advocates a return to dietetic treatment in vogue twenty-five years ago and since generally abandoned. It does not seem that enough evidence is presented to justify protein restriction over the often decade-long course of chronic glomerular nephritis. The description of the urinary sediment is highly original and the best with which the reviewer is acquainted. In a section headed "Abnormalities in Plasma Protein Formation," Addis accepts as an independent entity what is generally known as lipid nephrosis. He describes a cyclic course with complete clearing and recurrence; this the reviewer has not seen.

This book is an important contribution which will reward the close attention of serious students of Bright's disease and should leave an imprint on thought and practice in the field.

The Pathology of Nutritional Disease: Physiological and Morphological Changes Which Result from Deficiencies of the Essential Elements, Amino Acids, Vitamins, and Fatty Acids. By Richard H. Foellis, Jr., M.D., Associate Professor of Pathology, Duke University School of Medicine, Durham, N. C. Fabrikoid. Price, \$6.75. Pp. 291, with 72 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1948.

This readable and not too lengthy monograph is a scholarly and critical review of current knowledge of nutritional disease. The main emphasis is on the morphologic end results of the deficiencies, with perhaps less attention paid to biochemistry and physiology than some would like. Each of the forty or more indispensable nutrients is treated separately. Seventeen or eighteen of the ninety-odd metallic and nonmetallic elements are included, as well as ten of the twenty-odd amino acids, three closely related fatty acids and fifteen vitamins, in which there is evidence in one or more species for indispensability. The abnormalities in mammals provoked by deficiencies of these several substances are described. Illustrations add to the value of the book. They are numerous and excellent. Many of them are original. The bibliography of about 800 references covers most of the important literature. Although little attention is given to diagnosis of nutritional disease in man, the clinical aspects of the subject are not entirely neglected.

Much information has been accumulated in the last few decades to explain the action of the several essential nutrients, but much is wanting to complete the picture. A conspicuous gap in current knowledge is the lack of correlation of anatomic and biochemical changes. "Biochemists can thank pathologists for many of the leads which have opened up horizons in physiological chemistry; the reverse is true as well. But it is unfortunate that the twain so seldom meet." The author further emphasizes the point that as yet "no single nutrient has been simultaneously studied from the biochemical, physiological and morphological standpoints—something which is greatly to be desired."

Proteins and Amino Acids in Nutrition. Edited by Melville Sahyun, M.A., Ph.D. Cloth. Price, \$7.50. Pp. 566, with illustrations. Reinhold Publishing Corporation, 330 W. 42nd St., New York 18, 1948.

This is designed to supplement and extend an earlier volume edited by Dr. Sahyun, "Outline of the Amino Acids and Proteins." Since certain aspects of the intermediary metabolism of special amino acids were considered in some detail in the earlier volume, the treatment of certain phases of protein metabolism in the present volume is somewhat limited. These gaps are readily remedied if the two books are used jointly as a source of information on the metabolism and nutritional value of proteins and amino acids.

The opening chapter of the present volume is an extensive discussion of "Proteins in Nutrition (Historical)," which is supplemented by 18 photographs of men whose work is important in this field (from Magendie, 1781, to Lafayette B. Mendel, 1872). This historical treatment is not duplicated in English elsewhere to the knowledge of this reviewer. While it is difficult and perhaps unfair to single out individual chapters as of unusual excellence, 3 may be mentioned as unique. The chapter on "Caloric, Vitamin and Mineral Requirements with Particular Reference to Protein Nutrition" is concerned with an aspect of proteins which has assumed special importance in recent years and well merits the 39 pages devoted to it. Another chapter, "Economic Aspects of Food Proteins (66

pages)," discusses sources of protein food, proteins in diets of human beings, animals as food protein converters, economic aspects of food protein purchases, population in relation to food protein supplies and many other practical aspects of protein nutrition. Much of this material has not heretofore been assembled and thus organized. Mention must also be made of the fine discussion of the "Relation of Hormones to Protein Metabolism."

The clinician will find much of value in the 6 chapters devoted to problems of clinical interest, such as "Plasma Proteins and Their Relation to Nutrition," "Proteins Nutrition in Surgical Patients" and "Proteins as Related to Burns." The volume concludes with 2 chapters on "Toxins, Antitoxins and Related Substances" and "Filtrable Viruses."

An appendix which presents tables of food composition should be of particular value to dietitians. Each chapter concludes with an extensive bibliography, useful to students and research workers in particular.

The book can be highly recommended to the physician who wishes to extend his knowledge of proteins in nutrition as an up-to-date work of reference and to medical students and workers in nutrition and public health.

Human Physiology. By F. R. Winton, M.D., D.Sc., Professor of Pharmacology, University College, London, and L. E. Bayliss, Ph.D., Reader in Physiology, University College, London. Third edition. Cloth. Price, \$7. Pp. 592, with 248 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1948.

In this edition the two original authors (Drs. Winton and Bayliss) have become essentially editors, as in fourteen of the fifteen chapters other scientists and specialists are listed as primary contributors. This textbook of physiology for medical students is purposely condensed to about half the number of pages in the standard American text on this subject for students in medicine. The author-editors are convinced that medical students today are compelled to memorize and master too many facts at the expense of thinking and analysis: "The medical student is expected to know too much and to think too little." The condensation is achieved at the expense of elimination of much of the factual data on man and especially on other animals on which the generalizations and conclusions are based. One may question whether this is an aid to thinking on the part of our medical students. There can be no criticism of the endeavor to confine the data presented, so far as possible, to human physiology. But the inclusion of pertinent historical references and conclusive experiments on other animals is a stimulus to thinking, particularly for doctors, as long as we must depend on animals for the source and standardization of essential medicines, not to speak of the understanding and control of malnutrition, infections, cancer, etc. The illustrations are clear and helpful. The presentation is usually precise and factual. Some loose thinking is liable to slip into any textbook. This volume is no exception. We are told (p. 2) that: "perhaps the most characteristic feature of health is that a man can move about as quickly and for as long as he likes." This is not true. Competing athletes will testify to the contrary, and even the healthy man, trying to run from the charging tiger, is not lacking in will but in speed.

Nursing in Tuberculosis. By Louise Lincoln Cady, R.N. Cloth. Price, \$3.75. Pp. 481, with 64 illustrations. W. B. Saunders Co., 218 W. Washington Square, Philadelphia 5, 1948.

This book contains a large store of information of value to all nurses. The material is presented in four sections as follows: (1) "Hospital Aspects," (2) "The Nurse's Part in Treatment and Control," (3) "Nursing Aspects" and (4) "Educational, Social and Other Problems." In the first section appears a fine chapter concerning the nurse's work in the tuberculosis hospital and another on the public health nurse in the tuberculosis hospital. The final chapter in this section is devoted to prevention of tuberculosis among nurses. Following a discussion of the problem, some of the methods that have been employed to protect nurses are discussed, such as examining all patients admitted to general hospitals, the student health program of general hospitals, education of the patients and communicable disease technic, in which the author points out that such technic has been effective in the control of other con-

tagious diseases and therefore should be useful in tuberculosis. In the discussion of artificial immunization a few statements appear with which a great many workers in tuberculosis in this country may take issue. Among the 5 chapters under the second section is an excellent chapter on the nature of tuberculosis and another on epidemiology. The first chapter in the third section is entitled "Tuberculosis Case-Finding." This is devoted almost entirely to the roentgen method of case-finding. The chapter entitled "The Nurse's Part in Establishing a Diagnosis" contains information valuable to the nurse, pertaining to all of the diagnostic procedures, including bacteriologic studies and tuberculin tests. An excellent chapter is devoted to the general nursing care of the tuberculous patient. This is followed by a chapter on "Communicable Disease Precautions," in which the use of gowns and masks is described and evaluated. Considerable space is devoted to nursing care in collapse therapy, including artificial pneumothorax and the various surgical procedures. Oxygen therapy is also given considerable attention in this connection. Entire chapters are devoted to "Tuberculosis in Pregnancy," "Diabetes" and "Extrathoracic Tuberculosis," such as of the bones and joints and genitourinary tract. The last section of the book is composed of 8 chapters devoted to such subjects as "Health Teaching in the Home," "Mental Hygiene," "Rehabilitation of the Tuberculous Patient," "The Tuberculosis Clinic" and "Tuberculosis Legislation." This book can be recommended as a valuable addition to the libraries of students and graduates of nursing.

Kompndium der topischen Gehirn- und Rückenmarksdiagnostik: Kurzgefasste Anleitung zur klinischen Lokalisation der Erkrankungen und Verletzungen der Nervenzentren. Von Dr. Dr. h. c. Robert Bing, ordentlicher Professor der Neurologie an der Universität Basel, Basel. Tenth edition. Cloth. Price, 25 Swiss francs. Pp. 288, with 133 illustrations. Grune & Stratton, Inc., 381 Fourth Ave., New York 16; Benno Schwabe & Co., Klosterberg 27, Basel 10, 1948.

This is the thirteenth edition of Bing's compendium, and it continues to occupy first place in its value as a compend for students, physicians and postgraduates in neurology. It contains 130 illustrations and 3 plates. It is divided into three parts, namely: (1) localization of spinal cord lesions in transverse and longitudinal planes; (2) localization of cerebral lesions; (3) lesions of the cerebrum, the basal ganglia and the hypophysis. There is an excellent discussion on cerebral and basal aneurysms. This book is highly recommended to physicians who can read German.

The Anatomy of the Eye and Orbit, including the Central Connections, Development, and Comparative Anatomy of the Visual Apparatus. By Eugene Wolff, M.B., B.S., F.R.C.S., Ophthalmic Surgeon, Royal Northern Hospital, London. Third edition. Cloth. Pp. 440, with 323 illustrations. The Blakiston Co., 1012 Walnut St., Philadelphia 5, 1948.

The present volume proves that anatomy of the eye, together with general anatomy, is not a static subject. In addition to making a number of corrections the author has added more than 80 illustrations, the total number being 323, which makes for more ease in the study of this fascinating subject. Research in recent years has made it necessary for changes to be made in the descriptions of the ciliary muscle, the substantia propria of the cornea, the vitreous, the zonule of Zinn, the distribution of the lacrimal fluid, the mucocutaneous junction at the lid margin, the precorneal film, the retinal capillaries and the central connections of the visual apparatus. The volume has a beautiful format, many illustrations and clear and concise descriptions. It deserves a place in every library where the slightest interest in general anatomy, and specific anatomy of the eye and orbit, may arise.

Pathologie des zones pulmonaires. Par H. Warembourg, professeur agrégé à la Faculté de médecine de Lille, Lille, et P. Graux, médecin des hôpitaux de Lille, Lille. Préface du Professeur Jean Minet. Paper. Price, 380 francs. Pp. 141, with 70 illustrations. Masson & Cie, 120 Boulevard Saint-Germain, Paris 6^e, 1947.

A thorough knowledge of the anatomy of the pulmonary zones has assumed an importance not yet sufficiently appreciated, as a basis for the interpretation of anatomic and clinical findings in pulmonary and pleural disease. The work discusses in well illustrated text the various pulmonary zones and their interzonal barriers, and their relation to the branches of the bronchial tree. A clinical presentation of illustrative cases completes the book.

Chemical Russian, Self-Taught. By James W. Perry. Contributions to Chemical Education, Number 1. Cloth. Price, \$3. Pp. 221. Journal of Chemical Education, 20th and Northampton Sts., Easton, Pennsylvania, 1948.

According to the author of this volume, more chemical research is being reported in Russian than in any other language, except English. The need for chemists to be able to read chemical Russian has developed to a critical point. The author feels that the reading of chemical Russian can be learned by self instruction during spare time. This volume is offered as an aid. The first two sections of the book discuss aptitude for learning languages in general and methods for studying Russian in particular. The third section summarizes Russian word-building methods of importance with regard to scientific terminology. The fourth and fifth sections review inorganic and organic nomenclature. The final section of this book is an alphabetic glossary of technical terms of particular importance to chemists. It is suggested that the book be used by chemists in conjunction with a dictionary and a grammar. Callahan's "Russian-English Technical and Chemical Dictionary" is recommended.

Annata terapeutica 1947. M. Coppo, redattore capo; N. Allotta, direttore resp. "Clinica nuova," Supplemento annuale di aggiornamento terapeutico. Paper. Price, 1200 lire. Pp. 672, with illustrations. Clinica Nuova, Casella Postale 164, Rome, [n. d.]

This volume, written in Italian, contains in alphabetical arrangement a list of diseases with comparatively brief discussions on the diseases and measures of treatment. Interspersed throughout the book are advertisements for articles, some of which seem out of keeping with the title of the volume. For those in the United States the book provides an interesting reflection of therapy in some European centers; otherwise, it is of limited value to American medicine, as exception could be taken to some of the proposed treatments.

Rocky Mountain Conference on Infantile Paralysis, December 16 and 17, 1946, Denver, Colorado. Sponsored by the University of Colorado School of Medicine and Hospitals, and the National Foundation for Infantile Paralysis, Inc. Paper. Pp. 199, with illustrations. University of Colorado, School of Medicine and Hospitals, 4200 E. 9th Ave., Denver 7, 1947.

In December 1946 a conference on infantile paralysis was held under the sponsorship of the University of Colorado School of Medicine and Hospitals and the National Foundation for Infantile Paralysis. The proceedings of that conference are reported in this volume. The papers together with the discussions are presented through the use of planographing.

Many of the most able research scientists in the field of virus diseases, as well as prominent clinicians, presented papers or took an active part in the round table discussions. The subjects in this report include: "Epidemiology of Poliomyelitis," "Problems in the Field of Virus Infections," "Bulbar Poliomyelitis" and "The Care of the Polio Patient."

The material contained within this volume should be considered an indispensable addition to the library of each investigator or clinician who is currently concerned with any part of the problem of poliomyelitis.

Biology of Disease. By Eli Moschowitz, M.D. Mt. Sinai Hospital Monograph No. 1. Cloth. Price, \$4.50. Pp. 221, with 1 illustration. Grune & Stratton, 381 Fourth Ave., New York 16, 1948.

This monograph is a collection of essays on various diseases in which the author has had a special interest. Most of the essays had appeared individually in medical journals. Moschowitz attempts to integrate the concepts in regard to a number of diseases by elucidating the evolution of various diseases from their larval to their terminal states and also by pointing out the manifold interrelationships between many common disease syndromes. The topics selected for discussion vary from common diseases such as hypertension, arteriosclerosis and obesity to rarely encountered conditions such as myeloma, Libman-Sacks disease and polycythemia vera. The outlook of the author is broad and stimulating. Only those aspects of the diseases considered which are of special interest to the author are taken for discussion; the treatment is not exhaustive. The style is clear. The qualities which make this book distinctive are also its points of weakness; by attempts at broad integration some overgeneralization and speculation have occurred.

The 1947 Year Book of Endocrinology, Metabolism and Nutrition. Endocrinology. Edited by Willard O. Thompson, M.D., Clinical Professor of Medicine, University of Illinois College of Medicine, Chicago. Metabolism and Nutrition. Edited by Tom D. Spies, M.D., Chairman, Department of Nutrition and Metabolism, Northwestern University School of Medicine, Chicago. Fabrikoid. Price, \$3.75. Pp. 575, with 86 illustrations. Year Book Publishers, 304 S. Dearborn St., Chicago 4, 1948.

This book again is divided into two sections, the first being reserved for endocrinologic problems and the second for metabolic and nutritional considerations. In the endocrine section are abstracts of articles, with frequent comments by the editor, related to observations made in man and to some animal experiments considered to have a bearing on the interpretation of clinical phenomena. Among the glands about which there are articles are the pituitary, thyroid, parathyroid, adrenal, testes and ovaries.

The section on metabolism and nutrition has been arranged to permit grouping of the abstracted articles into those concerned with the pancreas and liver, alimentary tract, hemopoietic system, cardiovascular system, the brain and nervous system, genitourinary system, dermal, muscular and skeletal systems, malnutrition and therapy. The editors of the two sections have done a creditable job in choosing articles of interest primarily for the general practitioner, but which also may be helpful for the specialist. Like the other volumes in this series, the book will be welcomed by many as a useful addition to their libraries.

How to Help Your Child Grow Up: Suggestions for Guiding Children from Birth Through Adolescence. By Angelo Patri. Cloth. Price, \$4. Pp. 352. Rand McNally & Co., 536 S. Clark St., Chicago 5, 1948.

Dr. Patri needs no introduction, for he has possessed the reputation of a leader in education and child guidance for many years. The material in this book is an adaptation of the material used in Dr. Patri's widely syndicated newspaper column "Our Children." The book is divided into sections which are in turn divided according to subject. The subject index in the back of the book enables one easily to find references to such parental worries as eating habits, health, arithmetic, gambling, money and unmanageable child. The advice is always simple, sound and practical. This book is valuable reading for every parent. Because it discusses all those nonmedical problems which often worry parents more than the usual illnesses of childhood, this book should be on every pediatrician's and general practitioner's reference shelf.

"Onchocercosis" (enfermedad de Robles). Homenaje al tercer Congreso pan-americano de oftalmología, La Habana, enero 1948. Universidad de San Carlos, Facultad de ciencias médicas. Asociación oftalmológica de Guatemala. Paper. Pp. 257, with 74 illustrations. Guatemala, C. A., 1947.

In this study of the problem of onchocercosis in Guatemala, originally presented at the Third Pan-American Congress of Ophthalmology, the several phases of the problem of onchocercosis are discussed in individual chapters by Guatemalan physicians who have devoted considerable time to a detailed analysis of the disease in Guatemala. Historic, geographic factors, epidemiologic and important pathologic considerations are discussed in detail. Seventy-four excellent plates showing typical pathologic lesions of the disease are included. Because of the excellent initial work of Dr. Rudolph Robles in this disease, it has been suggested that the disease be named "Robles disease." The report is well annotated and contains many useful references to investigation of this disease in other areas.

Kinesiology Laboratory Manual. By Leon G. Kraus, M.S., Professor of Physical Education and Chairman of the Department, Northwestern University, Evanston, Ill. Looseleaf. Paper. Price, \$2.75. Pp. 177, with illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

This manual, in loose leaf plastic binding, is intended primarily for students of physical education, and for them it has definite value. It presents clearly and logically the origin, insertion, leverage and action of important muscles of the human body. The author has added an observation to each of them, especially with regard to their use in sports and other physical activities. The illustrations are excellent and easily understandable.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PNEUMOCOCCUS POLYSACCHARIDES

To the Editor:—What is the status of immunization against pneumococcus infection by means of the polyvalent pneumococcus polysaccharides? I have taken a somewhat skeptical attitude because of the great number of antigenic factors introduced.

M.D., New York.

ANSWER:—From the few studies published it appears that specific immunity against pneumococcal pneumonia can be achieved by vaccination with specific polysaccharides. In one report (*J. Exper. Med.* 82:445, 1945), a large group of persons was vaccinated with solutions of the capsular substances of pneumococcus types I, II, V and VII. Cases of pneumonia caused by these respective pneumococci were greatly reduced in number thereby, but the number of cases caused by other types of pneumococci was about the same as in former years. In a subsequent series of papers in the September 1947 issue of the *American Journal of Hygiene*, vaccination was shown also to reduce the carrier rate.

Because of the declining incidence of pneumococcal pneumonia in general, it is questionable if attempts to immunize persons routinely against it are worth while. Even during epidemics of minor infections of the respiratory tract such as colds, pharyngitis or influenza, the incidence of pneumococcal lobar pneumonia is usually only 1 to 1,000 or less. Under special circumstances it is, of course, important to prevent pneumonia, as, for example, (a) in small, localized outbreaks in institutions, military groups and schools, but by the time immunization is established, the outbreak is usually finished; (b) in patients with chronic diseases or in debilitated persons who are apt to be exposed to infection; (c) for the unusual type of person who has repeated attacks of pneumococcal pneumonia or other localization with the same or with a different type of pneumococcus, and (d) for members of a family or nurses strongly exposed to a patient with the disease.

"AMBERLITE"

To the Editor:—On Feb. 8, 1948 Exploring the Unknown, Research Institution of America, broadcast a program of a new treatment for hyperacidity and gastric ulcers with a resin which they claimed for superior to the alkaline aluminum hydroxide. Kindly advise whether there is any virtue in this treatment. If so, what firm manufactures it and under what name? Chas. W. Hartwig, M.D., Cockeysville, Md.

ANSWER:—Probably "amberlite IR IV" is the material in question. This is an anion exchange resin capable of reducing hydrogen ion concentration of gastric juice in vivo and in vitro, as well as inactivating pepsin. It has been shown to be practically nontoxic for rats or man when taken orally. For practical clinical use a fine mesh must be used to provide maximum exposure surface for absorption of acid. A 200 mesh material has generally been employed.

Early clinical trials indicate that "amberlite IR IV" is a quick acting, effective acid neutralizer that will relieve the pain of peptic ulcer. The resin is insoluble and does not disturb acid-base balance. Because of the undesirable formaldehyde-like smell and the gritty, sandy taste, capsules may be more desirable than the straight powder form of administration. Though small doses, as low as 0.25 Gm., will reduce acidity, this reduction is apparently transient, and large repeated doses, as high as 0.60 Gm., need be given to reduce the acidity to effective low or negative values. The ideal dosage has not yet been determined. Recurrences and complications have occurred with resin therapy, even while the material was being taken. The effects of neutralization are transient as with other antacid therapy.

It is unwarranted to conclude at this time that "amberlite IR IV" is superior or even equal to the usual antacids for neutralization of gastric acidity in the clinical management of peptic ulcer. Further carefully controlled studies by competent clinical observers are needed for proper evaluation. The resin is still limited to investigational use, and may be obtained from the National Drug Company, Philadelphia, or the Resinous Products and Chemical Company, Philadelphia.

CURE IN SYPHILIS

To the Editor:—A white man aged 21 years acquired a chancre in May 1946. He was treated for one week with multiple injections of penicillin (amount unknown, but given in a United States Army hospital). At that time his blood serologic reaction was negative. All subsequent blood serologic reactions have been negative. Spinal fluid serologic reaction was negative one year ago, and is negative now. Evidence of any type of recurrence is absent. 1. What is the likelihood of relapse? 2. What further testing should be done, and at what interval? 3. May he marry now; if not, when? 4. If he marries now, what tests, if any, should be done for his wife (a) if pregnancy occurs and (b) if it does not?

M.D., Massachusetts.

ANSWER:—1. It is possible but not likely that a relapse will occur in this case because the most dangerous period from the point of view of relapse is in the first two years after treatment has been completed. His syphilis was treated at the most opportune time; i. e., during the seronegative chancre stage. 2. There should be a general physical examination and blood test performed every six months for about five years. It is not necessary to examine the spinal fluid again in this case. It is a good working rule that if for five years after completion of treatment all tests give repeatedly normal results, the patient may be considered as cured for all practical purposes. 3. He may marry at any time. 4. (a) During pregnancy the wife's blood should be tested in the first month and again in the sixth month. (b) In the interest of caution, the wife's blood should be tested three to four months after marriage.

CHRONIC ALCOHOLISM

To the Editor:—I have several patients for whom their families have requested treatment for chronic alcoholism. I have started the use of the McBride treatment of increasing doses of atropine and strychnine in an effort to render the taste of liquor unpleasant. Would you please advise on the value of this treatment or of better therapy. Can you recommend centers or physicians in the Southwest who make a specialty of this treatment?

M.D., New Mexico.

ANSWER:—Strychnine without atropine has been used by Perisson (*Union méd. du Canada*, 72:317 [March] 1943), and an evaluation of the treatment may be found in Queries and Minor Notes, J. A. M. A. 126:138, 1944. The answer to this query points out that alcohol in the inebriated person is completely oxidized or eliminated within twenty-four hours after he has stopped drinking, so that after this it is no longer a question of combating the narcotic action of the alcohol by strychnine. Also, the period of heightened nervous irritability following alcoholic excesses might be further aggravated by strychnine. The addition of atropine to strychnine might have some slight value as aversion treatment. The aversion treatment which appears to be effective in about 50 per cent of the cases is that developed by Voegtlin and his associates. Even with this method the recent writings of Voegtlin and Lemere (*Quart. J. Stud. on Alcohol*, 2:782-785 [March] 1942) indicate that considerable additional psychotherapy is usually necessary to insure success. These authors reported unfavorably on the use of strychnine and atropine. The information available regarding the McBride treatment would indicate that no centers or physicians using this treatment in the Southwest or elsewhere should be recommended.

KELOID

To the Editor:—It is my impression that excision followed by roentgen therapy is the most effective form of treatment for keloids. What is the cause of this condition, its incidence in the white race and other forms of therapy?

Gale D. Johnson, M.D., Dunn, N. C.

ANSWER:—The cause of keloid formations is unknown. The Negro race is especially subject to them, but they may appear in any one at any age and equally often in the sexes. It is believed that those which arise spontaneously follow insignificant injuries, such as insect bites. Otherwise, these growths may follow injuries, burns or infections. Certain varieties of the latter, such as scrofuloderma, are prone to keloidal complication.

The most effective treatment is radiotherapy. Roentgen rays or radium may be used. When the keloids are of recent origin and small, radiation alone suffices in many instances. When they are older and large, it may be necessary to excise them and to follow the surgery by using roentgen rays or radium. Some keloids, such as those following gasoline, hot water and chemical burns, may require only excision or grafting in addition if extensive. Ordinarily, surgical treatment alone without radiation, however, invites return of the keloid in somewhat larger dimensions. Other methods for removing these growths have been described and found useful. None of them, however, is reliable, and radiotherapy remains the treatment of choice.

ECLAMPSIA

To the Editor:—The literature generally describes the typical, pathologic findings in eclampsia as a periportal necrosis of liver due to thrombosis of the smaller portal veins. Has experience been reported on the use or value of anticoagulants in combating this lesion?

Charles E. Galt, M.D., Carlsbad, N. M.

ANSWER.—In a recent article J. Van S. Maeck and H. Zilliacus (*Am. J. Obst. & Gynec.* 55:326-331 [Feb.] 1948) present evidence from the literature to show that in pregnancy, and especially in toxemia of pregnancy, at least one substance (fibrinogen) and possibly a second (thromboplastin) is present in increased amounts and that in eclampsia the coagulation time of the blood is decreased, thereby predisposing to generalized, diffuse thrombi. It is logical to assume that heparin in part, because of its anticoagulant action through its ability to neutralize thromboplastin and fibrinogen (?) and because of its antiagglutination effect, can inhibit the pathologic changes and favorably influence the clinical findings. A case of toxemia is presented in which abrupt and decided improvement which continued was observed nine hours after treatment intravenously with 150 mg. of heparin. Three additional cases of toxemia treated in Finland are mentioned. In 1 of these, a case of severe toxemia and eclampsia continuing post partum, definite improvement was noted after heparin therapy at a time when the prognosis was exceedingly grave.

However, caution must be exercised in the use of anticoagulants in cases of toxemia, in which there is nearly always an hepatic disturbance and also some renal involvement. According to N. W. Barker (*M. Clin. North America* 29:929-935 [July] 1945) among the contraindications to the use of "dicumarol" are the presence of definite hepatic insufficiency and the presence of definite renal insufficiency because these conditions greatly prolong and increase the effect of "dicumarol."

UMCKALOABO

To the Editor:—Can you give me any information about a drug called "Umckaloabo"? I understand that this was mentioned in a book called "Burma Surgeon" and is supposed to be of some value in the treatment of tuberculosis; at least my information is that it is used for this purpose in Burma.

James W. W. Dimon, M.D., Utica, N. Y.

ANSWER.—"Umckaloabo" probably refers to "umckaloabo," a plant or group of plants of somewhat dubious origin. Apparently, about 1900, a quack by the name of Charles H. Stevens brought some plants from South Africa to England, from the bark of which he prepared an extract which was exploited for many years as a "consumption cure." A complete history of the Stevens consumption cure was published by the Bureau of Investigation of the American Medical Association in *THE JOURNAL*, 95:951, 1930. The extract used by Stevens was claimed to be "umckaloabo."

An article in *Dental Cosmos*, 57:1366, 1915, stated that "umckaloabo" refers to a group of South American herbs employed as infusions by the natives for all diseases of an infectious nature. A 5 per cent solution of the native tincture has been reported to be antiseptic. Bernoulli and Thomann in their book "Übersicht der gebräuchlichen und neueren Arzneimittel," 1946, also mentioned "umckaloabo" as a fluid extract of a South African plant, which has been claimed to be useful in infections.

Apparently the term "umckaloabo" does not refer to a specific substance or even to a specific plant but has been applied to various plants and extracts obtained in widely separated parts of the world. A search of the scientific literature for the past fifty years reveals no information with regard to its successful use in tuberculosis.

DIETARY LAW

To the Editor:—Is there any gastric distress and consequent gastric disturbance from using both animal and liquid albumin (casein—albumin) at one meal? The Jewish dietary laws do not allow the consumption of meat and dairy products at the same time.

M.D., Pennsylvania.

ANSWER.—While substantial reasons are now apparent for many of the old dietary laws, some of them are not supported by evidence. We know of no reason for avoiding the ingestion of meat and milk or fish and milk at the same meal. There is nothing in either of these combinations to make them dangerous when combined, unless one or both of the combination is contaminated.

ACETYSALICYLIC ACID

To the Editor:—Is it possible to make a solution or a suspension in which acetylsalicylic acid will remain stable?

E. A. Fry, M.D., Columbus, Ohio.

ANSWER.—Acetylsalicylic acid hydrolyzes in the presence of water to free salicylic and acetic acids. This action is hastened in aqueous mediums containing either acid or alkaline constituents. The decomposition of acetylsalicylic acid may be inhibited somewhat by substances such as glycerine or sugars. (A relatively stable solution may be made by dissolving the required amount of acetylsalicylic acid in a mixture of equal parts of alcohol and glycerine.) It is considered impractical to make a solution or a suspension of acetylsalicylic acid which will remain completely stable; for that reason it is suggested that sodium salicylate might be used in place of acetylsalicylic acid.

CONGENITAL SYPHILIS

To the Editor:—The serologic reactions of a young married woman, now pregnant, with congenital syphilis without physical manifestations were not altered by adequate antisyphilitic therapy. She is now receiving additional antisyphilitic therapy with penicillin, oxophenarsine hydrochloride and bismuth compound. What procedure should be followed to determine whether or not the expected infant is affected? In view of the mother's positive serologic reactions I presume that the cord blood and the infant's blood may show positive serologic reactions.

Benjamin Trachtman, M.D., Brooklyn, N. Y.

ANSWER.—It would be most unusual for this infant to be born with syphilis: (a) because the mother will have had sufficient treatment to protect the infant, and (b) because undoubted instances of third generation syphilis are extremely rare. The infant's status may be established by means of repeated blood tests, physical examination and roentgenograms of the long bones.

The blood of both mother and infant should be examined by a quantitative method. If the infant's blood gives a positive reaction even though there is no syphilis, the titer should be as low as or lower than that of the mother and there should be a negative reaction in a few weeks. If the titer of the infant's blood is greater than the mother's and if it continues to rise, it indicates that syphilis may be present. All tests should be performed in the same reliable laboratory.

The clinical manifestations of congenital syphilis are usually apparent by the third or fourth week and consist of an eruption of syphilids, snuffles, rhagades, an enlarged spleen, cracked lips and a peculiar cry.

Roentgenograms of the long bones for evidence of osteochondritis should be taken routinely in the first six weeks of life. According to Stokes, progressing osteochondritis which may occasionally be accompanied by periostitis occurring in a seropositive infant during the first six weeks of life may be considered as establishing a diagnosis of syphilis. One must not confuse the syphilitic changes with epiphyseal and periosteal lesions that may be produced by other conditions, particularly by bismuth salts used for the treatment of the mother during pregnancy.

RABIES VACCINE REACTION

To the Editor:—Will prophylactic rabies vaccine cause suppurative meningitis? A white man aged 35 years became lethargic, then unconscious; had a stiff neck, a temperature of 103 to 105 F., a white blood cell count of 21,000 to 25,000 and spinal fluid showing 300 plus pus cells per cubic millimeter; 90 per cent polymorphonuclear leukocytes and no bacteria on smear. Two spinal fluid cultures were negative. Illness occurred following nine prophylactic rabies injections. Vaccine was provided by the U. S. Public Health Service at Little Rock, Ark. (ultraviolet killed preparation). Pellicle formation occurred in the spinal fluid. The patient's recovery was uneventful after treatment with streptomycin and penicillin intramuscularly and intrathecally and administration of mixed sulfadiazene, sulfathiazole and sulfamerazine. Residual effects were absent. Apparently unusual in his clinical picture was a lethargic state without evidence of excitement.

Karlton H. Kemp, M.D., Texarkana, Ark.-Texas.

ANSWER.—Prophylactic rabies vaccine will not cause suppurative meningitis. This type of meningitis is always due to bacterial invasion and not virus infection. Your patient had an attack of encephalomyelitis due either to a postvaccinal rabies reaction or faulty vaccine, and an attenuated form of rabies resulted. From the history given your patient probably had an attack of postvaccinal encephalomyelitis involving the cerebrum primarily. Although there are quiet attacks of rabies (without excitement) because of early paralysis, your patient on the basis of history alone did not have rabies but a reaction from the vaccine.

HEREDITY OF HARELIP

To the Editor:—A married female patient was born with a harelip. She and her husband desire children. Is the incidence of harelip increased in the offspring of "harelip" mothers?

Louis N. Speer, M.D., Ottawa, Kan.

ANSWER.—Harelip frequently occurs sporadically or as a single case in families. Sanders reports from Holland more than 200 such cases. However in about 50 per cent of all his cases 2 or more cases occurred in each family, sometimes with a generation skipped—hence indicating a recessive mode of inheritance. Many other pedigrees give evidence of heredity. Many of these permit no statement regarding the mode of inheritance. In a recent monograph on harelip and cleft palate by Fogh-Anderson the author wrote: "It is impossible to demonstrate with certainty any other etiologic factor than a hereditary predisposition." Regarding the mode of inheritance he concluded that the most likely manner of inheritance is that of a "conditioned dominant" with some sex differences (more males than females) and with homozygotes manifesting the condition more often than heterozygotes. In other words he considers the anomaly largely hereditarily determined with the condition sometimes occurring in successive generations and sometimes skipping a generation. It is difficult to advise relative to the family in question. A check should be made of relatives. If no other occurrences are found the probability of its appearing in a child would appear to be low.

DENTAL CALCIUM DEPOSITS

To the Editor:—What can be done besides scaling for a female patient 17 years of age who deposits calcium on teeth so rapidly it must be removed about every two weeks? Blood calcium is 8.9 mg.

Charles H. Edel, M.D., Norwalk, Ohio.

ANSWER.—The approach to this problem is twofold. First, the patient should be given a thorough physical examination including urinalysis and blood studies to rule out possible systemic factors. The diet should be adjusted to include an abundance of alkaline ash and fibrous foods. Natural detergents such as fresh fruits should be prescribed. Frequent, small meals rather than widely spaced, heavy ones are suggested. The patient should be taught proper mechanical interference with the process which causes the hardening of the calculus. A stiff, natural bristle tooth brush can remove the organic matrix of the calculus while it is still in the soft state. It is necessary that the patient thoroughly clean the teeth once in every eight hour period. Thorough cleansing will prevent accumulation of calculus. Warm, normal saline mouthwashes may be used as an adjunct.

SPASTIC PARALYSIS

To the Editor:—What is the treatment of spastic paralysis? What solution is injected subcutaneously by some neurologists for the relief of spasm in this disease? Is tuberculin used for this purpose?

M.D., West Virginia.

ANSWER.—The treatment of spastic paralysis is varied. For the most part, it consists of reeducation through physical therapy, occupational therapy and exercises. Curare or one of the synthetic preparations similar to curare, such as "intocostin," has been used by subcutaneous injection to help to relax the hypertonicity of the muscles. This drug should not be used by anyone who is not fully familiar with its dangers. There is no evidence at all that tuberculin is of any value for this condition.

PENICILLIN DUST

To the Editor:—I have had so many inquiries regarding the penicillin dust treatment (home treatment) since articles have appeared in the daily papers that I should like to know whether such units are obtainable.

Libuse Bliss, M.D., Algonquin, Ill.

ANSWER.—The penicillin "dust" or "mist" treatment probably refers to aerosolized penicillin for the treatment of acute and chronic paranasal sinusitis and acute and chronic bronchopulmonary disease. Crystalline penicillin G can be dissolved in isotonic sodium chloride solution and placed in a nebulizer and sprayed into the nasal passages or into the bronchi and lungs. One hundred and fifty thousand to 1,000,000 units daily in divided doses have been used in acute and chronic infections. The penicillin is given this way every two or three hours. Various types of nebulizers have been employed. Penicillin is available in 50,000 unit tablets that can be inserted directly into the nebulizer. One-half to 1 cc. of sodium chloride solution is

then added, and, after the penicillin goes into solution, it can be nebulized. Crystalline penicillin tablets are provided by several manufacturers. The best review of the subject of penicillin aerosol therapy can be found in the article by Garthwaite, B.; Barach, A. L.; Levenson, E., and Rader, D., *Am. J. Med.* 3:261, 1947.

DIABETES INSIPIDUS

To the Editor:—A 30 year old white married woman has diabetes insipidus of six months' duration following normal delivery of a 10½ pound (4,763 Gm.) baby. In addition to intense thirst and passing 5 to 6 quarts of urine daily of specific gravity not over 1.004, she has obstinate constipation, frontal headaches of a fairly severe type and frequent recurring type, and amenorrhea of four months' duration. Physical examination, including neurologic, is essentially normal. The basic metabolic rate, blood cell count, sedimentation rate, phenolsulfonphthalein reaction and urine are otherwise normal; blood sugar, nonprotein nitrogen and roentgenogram of the skull were all normal. Please advise and give references regarding amenorrhea and severe headache.

Harry Parks, M.D., Atlanta, Ga.

ANSWER.—The exact cause of diabetes insipidus has not been determined, but it is certain that there is a deficiency or absence of some pituitary principle, most likely the antidiuretic principle of the posterior hypophysis. Experiments have shown that only those lesions of the hypothalamus which lead to atrophy of the posterior lobe result in diabetes insipidus. Confirmatory but not conclusive evidence of the role played by the posterior lobe in this disease is the clinical improvement observed after the use of posterior pituitary extracts, particularly the "pitressin" component. The amenorrhea cannot be explained on the basis of posterior lobe insufficiency. If, however, there is an associated hypofunction of the anterior lobe involving the gonadotrophic factors, this can cause amenorrhea. This patient may have a mild case of postpartum necrosis of the anterior pituitary, a condition well described by H. L. Sheehan and R. Murdoch (*J. Obst. & Gynaec. Brit. Emp.* 45: 456-489 [June] 1938). In nearly all of these cases, however, the women have postpartum hemorrhage and collapse at the time of labor. Two cases of diabetes insipidus in association with postpartum pituitary necrosis were reported by A. W. Spain (*J. Obst. & Gynaec. Brit. Emp.* 53:223 [June] 1946). In both these cases there was an extreme degree of polyuria, and at necropsy it was found that there was necrosis in both the anterior and posterior lobes of the pituitary body. Spain says that the recurrence of symptoms of diabetes insipidus in association with postpartum necrosis of the pituitary has not previously been commented on. Significantly in the experimental animal the polyuria following ablation of the posterior lobe is relieved by removal of the remainder of the gland. This suggests that some action of the anterior lobe hormones is necessary in the production of the diabetes insipidus syndrome. In Spain's 2 cases a small proportion of the anterior lobe cells survived.

Of course, the amenorrhea and the headaches may have nothing to do with the diabetes insipidus. There need be no concern about the amenorrhea per se, but the severe constipation and the headaches must be treated as well as the diabetes insipidus. The headaches may disappear after the use of posterior pituitary preparations.

SPONTANEOUS HEMOPNEUMOTHORAX

To the Editor:—The query on Spontaneous Hemopneumothorax in The Journal of June 26, 1948, Queries and Minor Notes, page 822, and its reply are quite interesting. As indicated in the reply, many cases of spontaneous hemopneumothorax are not reported. The question concerning "the statistical incidence of such an entity (spontaneous hemopneumothorax) compared to pneumothorax alone" is difficult to answer exactly. In a period of several years, we have observed 84 cases of benign idiopathic spontaneous pneumothorax (nontuberculous). In this group there were 5 cases of hemopneumothorax, or, roughly, 6 per cent.

The author of the reply states that "more than two thirds of the reported cases (spontaneous hemopneumothorax) have been complications of pulmonary tuberculosis." We believe that many cases reported as being tuberculous actually are not. In our personal series of 36 cases of tuberculous spontaneous pneumothorax, gross blood was not observed in the pleural cavity. In fact, the 5 cases of spontaneous hemopneumothorax that we have seen have all been of the benign idiopathic type (Benign Idiopathic Spontaneous Pneumothorax, *Am. J. M. S.* [April] 1948; Benign Idiopathic Spontaneous Pneumothorax and Tuberculous Spontaneous Pneumothorax, to be published).

THE HEALTH DEPARTMENT AND THE FOOD OF THE PEOPLE

Chairman's Address

ROBERT H. RILEY, M.D.
Baltimore

It is difficult indeed adequately to express how deeply I appreciate the honor of presiding over this section. For many years, bearing various names and under the chairmanship of a long list of distinguished physicians, the annual meetings of this group have afforded a valuable opportunity for those engaged in the administration of official health agencies and those engaged in the practice of preventive medicine to meet together for a discussion of the problems which confront them both.

During the period of my connection with this section, the fields of preventive medicine and public health have moved forward so rapidly that only those of us whose service covers a period of more than one or two decades can recognize how far we have come. Every field of human knowledge, with the possible exception of mathematics, has made more scientific and technologic progress in the last few decades than during the whole of previous history, and public health and preventive medicine have contributed more than their full share in this development. This new knowledge has resulted in profound alterations in the way of life of the human being, and the contribution of preventive medicine to these changes has been most important of all.

It is my purpose at this time, however, to discuss developments in only one small sector of the whole field of public health, that of human nutrition. In that field I shall try to review the changes which have already occurred and to look forward to the problems with which the future is pregnant, so far as they can now be foreseen.

The changes in human food habits during the last three decades have been so rapid, so profound and so powerful in their actual and potential effect on the well-being of the race that they should be far better understood than is now the case. Some of us here can, for example, remember when the food supply of the nation was in large part produced within a few miles of the place of its consumption. Some have, in fact, loaded a sack of corn on the back of a horse or mule and ridden with it to the grist mill and then watched

the grain poured into the hopper and in a moment seen the meal running smoothly back into the sack from which the corn had just been poured. I can remember when the fruits and vegetables on sale even in the larger cities were almost all produced on nearby farms. They were brought to the markets of the city and there sold to the consumer by the farmers who had themselves grown and harvested them. Tropical fruits were a great luxury, available, except to the very rich, only on very special occasions.

The supply of milk was from varied sources and was wholly unregulated. Many families in the cities kept one or two cows for their own supply and sold the surplus to their neighbors over the back fence. These one-cow dealers, as they were called, were a problem of serious moment in the early campaigns of milk sanitation. For the rest, the public supply of milk was in great part produced in small dairies located within the city itself, or in the nearby suburbs, and sold by the producer from his own wagon as he made the daily rounds of his customers. Meat was also a local product, from animals killed in slaughter houses within the community and sold as soon as possible after slaughter.

A few foods had of course always come from distant sources; sugar, molasses, spices and condiments were articles of ocean commerce for centuries. The opening of the West moved the center of the nation's grain supply and of milling to west of the Mississippi. The preservation of fruits and vegetables by heating and sealing has a long history. The first experiments were made in France during the Napoleonic Wars, and actual industrial canning began in the United States in 1819. It was the perfection of this process that really began the revolution in food habits.

But with these exceptions, the mass of the food of our fathers and grandfathers was produced close to the place of its consumption and was subjected to the simplest and most necessary processing only.

We can, it is true, remember those early days without nostalgic longing for their return. The vegetables produced on nearby farms were not always of good quality and except for cabbage and turnips were available only for a brief season each year. The milk was dirty, of poor keeping quality and not infrequently dangerous. The meat was tough and stringy, and even its relative cheapness was not adequate consolation for its poor quality. Fruits were limited in amount and were, except for apples, available only for a short period each year. To those who lived in those parts of the country where cornbread was a staple diet, it is only the corn meal of the old days the disappearance of which is to be regretted.

Director, State of Maryland Department of Health.
Read before the Section on Preventive Medicine and Public Health at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

About the time when Benjamin Harrison became President of the United States, the tremendous increase in the population of the cities began to produce changes in the production and distribution of the food supplies of the nation. The invention of roller mills had made possible the production of flour of more agreeable appearance than was possible under older methods, and this flour rapidly drove from the market the product of the smaller local mills.

Similarly, the production of range cattle in the far West resulted in the establishment of great centers for the slaughter of cattle and in the development of methods for the shipment of meat and meat products to distant consumers. When "western beef," as it was called, was first introduced in the markets of the eastern cities, it was regarded with considerable disfavor. Consumers imagined that they could taste the preservatives which they wrongly believed had been used to make its shipment possible. In the beginning only its lower price commended it to the public.

The crowding of the cities made it impossible to continue to produce an adequate amount of milk within or near the city limits, and technologic methods were devised for shipping milk long distances. Successfully to manage this business required the creation of large corporations and the development of depots for collecting milk in rural areas and for distributing it in the cities. The use of refrigerated cars for the shipment of meat led quickly to the shipment of citrus fruits and vegetables in the same way. It was soon found profitable to raise each fruit or vegetable in that part of the country where climate and soil were most favorable to its production, and although market gardens near the cities have never quite disappeared, the great bulk of fruit and vegetable production was moved to areas far distant from the places of maximum consumption.

These changes were the inevitable result of the advances in horticulture, in food technology and in transportation, and without them the development of our present civilization could not have taken place. They brought, however, certain dangers to the health of the people, which made necessary the development of systems of protection of equal complexity. The most pressing were, of course, those connected with the production and distribution of milk. It was not difficult for the large corporations which engaged in the business of collecting and distributing milk to produce a product far cleaner and of better keeping quality than that coming from the neighborhood dairies of the past. However, the mingling of milk coming from many cows and its distribution by the larger companies to thousands or even hundreds of thousands of persons brought dangers which had previously not existed. The occasional infection of these large supplies of milk and milk products gave rise from time to time to epidemics involving thousands of cases of typhoid, scarlet fever and septic sore throat. The shipment of meat and of certain other products led to the use of preservatives, not all of which were entirely innocuous. The great commercial orchards and truck farms began to use insecticides in large quantities, and some of these were highly toxic and at least potentially dangerous to the health of those habitually using products in the growth of which these poisons had been employed.

The health departments of the nation reacted promptly and, in general, effectively to the challenge of these new conditions. The almost complete control

of bovine tuberculosis, the inspection of all establishments where milk and its products were produced, distributed or sold and the enactment of ordinances requiring pasteurization of public milk supplies soon resulted in so safeguarding most of the nation's supply of milk that the dangers of wide distribution were almost completely controlled. The improved safety and quality resulted in a large increase in the consumption of milk, and a most significant contribution was thus made to the public health.

It was indeed fortunate that the federal government entered the field of food control soon after the beginning of this period of great change. Its first activities were in connection with meat inspection. Foreign countries threatened to interdict the shipment to them of American meat products, because of the fact that a large proportion of the pork shipped abroad at that time was found to be trichinous. It had not been deemed necessary to inspect pork products in the United States, since it was the habit in America to cook pork long enough to insure the destruction of trichinae. To meet this situation, the federal government established a system of inspection for meat slaughtered in the larger abattoirs of the country and destined for shipment overseas. It was not long before this inspection was extended to meat shipped interstate in the United States.

In the very first years of the twentieth century, Dr. Harvey W. Wiley, then the Chief of the Bureau of Chemistry of the United States Department of Agriculture, interested himself in the question of the adulteration of foods shipped in interstate commerce. Although Dr. Wiley was a man of extraordinary energy and courage, it was only after many years of effort that he succeeded in securing the passage of the Federal Food and Drug Act of 1906. The conditions which this act was designed to correct were not for the most part tremendously important by modern standards, but it was an exceedingly fortunate thing that the act itself was passed and that standards of purity and freedom from deleterious substances of our food supply were established and enforced by the federal government.

The passage of the federal act was followed, as is so often the case, by parallel legislation on the part of the states. Many of the state laws passed at this time, however, placed the enforcement of the whole system of food control in the hands of the department of agriculture rather than that of health. This fact, together with the long failure of the older city departments of health to develop adequate and effective systems of food inspection, gave food sanitation so low a position in the minds of the public health profession that it has even now not received the recognition it deserves. The demonstration about this same time of the tremendous importance of the accessory food factors in the nutrition of human beings and domestic animals and the widespread popularization of the facts have tended still more to obscure the importance of continuous, complete and effective control of all those foodstuffs which are processed in any way before reaching the ultimate consumer.

There is certainly no need in this company to review the arguments for an improvement in the diet of our people. The new knowledge of the importance of vitamins and of certain mineral substances to health and physical vigor is now known to all intelligent persons in every civilized country. The task remaining is to apply this knowledge to those who have not yet

been reached by the flood of propaganda on the subject which has been poured forth in recent years. The success of the British government in maintaining the health of its whole people and in actually improving the physical status of its children during the late war, in the face of serious shortages of many foods, is proof positive of the need for the better utilization of the abundant food supplies of this country and in particular of the enormous importance of insuring to every expectant mother and every growing child a diet which in amount and content will make possible the fullest and most healthful development. This is the unfinished task in nutrition.

There are still, however, unfinished tasks in connection with the safety and sanitary quality of our food supply. The war waged by our growers of foods of all sorts on their insect enemies is never won, and it will probably continue as long as there are both human beings and insects on this little planet. Modern transportation is being utilized as well by the insect as by the human population of the earth, and new pests are constantly appearing in areas where they had not before been known. In this war, new weapons are constantly being developed and the old weapons are used in steadily increasing amounts. It was not very many years ago that arsenic began to be used as a spray for apples. The danger that the average citizen would receive a toxic amount of arsenic was not at first sufficiently serious to give rise to much concern. Since this early beginning, however, it has proved necessary to use arsenic in the commercial production of one after another of our fruits and vegetables, and the danger to the consumer is thus constantly increasing. It seems probable that insecticides free from toxicity to human beings will in time replace the present dangerous substances. It will always be necessary, however, for the health department to protect the interests of the individual consumer who has no means of knowing the danger to which he is subjected and is always poorly represented when any question of legislation is under consideration.

When the replacement of the original Federal Food and Drugs Act by what is now called the Federal Food, Drug and Cosmetic Act was pending before the Congress of the United States, the interests of the public were presented to the committee by the representative of the Federal Food and Drug Administration, whose motives were plainly suspect of the committee, and by the three physicians who were called "the three professors," who appeared voluntarily as witnesses in behalf of the bill. In opposition were several hundred lawyers, lobbyists and technicians of the various food-producing and processing interests involved. Each one of these paid lobbyists was fully aware of the effect of the bill on the interests of his own client and was prepared to expend all the time, energy and money necessary to protect those interests. No administrative health officer appeared at these hearings.

What has been said about insecticides applies equally to a wide variety of other chemical substances which have been developed and which are now being used in the processing of food on a commercial scale. Until Mellanby's demonstration of the fact that flour treated with nitrogen trichloride, the so-called "agene," produced hysteria in dogs, few if any even of our best informed health officers were aware of the fact that a large proportion of all flour now sold on the American market is treated with this powerful chemical agent.

There is as yet, of course, no evidence that the "agenizing" of flour has produced any ill effects on our human population, but Mellanby's observations have been confirmed and extended in this country, and no one as yet knows the effect on human beings of the prolonged and regular use of "agenized" flour, or whether or not there will be remote and serious results from its occasional use by so large a part of the population.

"Agene" is very much in the limelight at the moment, but it is by no means the only substance used in this country in the processing of flour. Chlorine, nitrosyl chloride, benzoyl peroxide and the oxides of nitrogen are all used for bleaching flour and for additional aging effect. Potassium bromate is used as a conditioner, to make the flour easier to handle and to produce loaves of greater volume than is possible without the addition of this agent. Sodium bicarbonate, calcium phosphate and sodium acid pyrophosphate are also added to certain flours to produce one or another effect.

In the processing of evaporated milk, disodium phosphate, sodium citrate and calcium chloride are used as stabilizers. In the making of cream cheeses, gum karaya, gum tragacanth, carob bean gum, gelatin and algin are used to prevent the leakage of moisture from the product. In the making of preserves, jams and jellies, lactic, malic and tartaric acids are used to increase the acidity of the product and sodium citrate and potassium tartrate are used as buffer salts to prevent its too rapid jelling. This list of products now regularly in such use could be extended to great length, and, in addition, a large number of new products are now being used experimentally. It should be made clear that up to this time there is no evidence that any of these substances is known unfavorably to affect the health of consumers of the product. The Food and Drug Administration has actively interested itself in the subject and has formulated stringent regulations for controlling the use of all such substances.

Surely it would seem that this situation should be a source of concern to every state and local health officer in this country and that the efforts of the federal government to control it should be aided and encouraged in every possible way. When it is proposed to use a new substance of this kind, the representatives of the food industry are at once mobilized and every possible scrap of evidence in favor of the use of the product is assembled and presented to the official agency. The millions of consumers whose health is placed in possible danger have no knowledge of the fact that their interests are in jeopardy and no means by which these interests can be represented. This important field deserves far more attention at the hands of all health officers than it has up to now received.

The nation's food is more than ever, therefore, the concern and responsibility of our health officials. Its control has passed far beyond the condemning of spoiled meats, fruits and vegetables and making perfunctory inspections of restaurants. These classic functions must, of course, continue to be performed and should be done as well as our existing facilities make possible. There is, however, another and higher duty which we must recognize and another responsibility we must assume, and that is to make sure that in the enormous business of producing, processing and distributing the food supply of our great population, the interest of the consumer and particularly the health of the consumer must always come before the convenience or the profit of those who supply it.

METHODS OF PROTECTION AGAINST HOMOLOGOUS SERUM HEPATITIS

I. Studies on the Protective Value of Gamma Globulin in Homologous Serum Hepatitis SH Virus

Philadelphia

Antigenic differences between certain strains of infectious (epidemic) hepatitis virus (IH) of relatively short incubation (about eighteen to forty days) and certain strains of serum hepatitis virus (SH) of relatively long incubation (about sixty to one hundred and fifty days)¹ have been conclusively demonstrated. The data of Oliphant,² suggesting immunologic similarities in such viruses, could well be explained by the facts that: (1) the virus, designated by Oliphant as that of epidemic hepatitis, had a long incubation period (about seventy-five days), (2) thus, it actually may have been a strain of serum hepatitis virus, SH, rather than one of epidemic hepatitis, IH, and (3) a cross immunity with his designated serum hepatitis virus, SH, therefore would not have been surprising.

The confusion concerning the origin of such strains of hepatitis virus can best be clarified by study of their immunologic behavior in experimental subjects. It thus would appear important from the viewpoint of experimental studies that virus agents in infective materials should be only tentatively designated by the term "infectious hepatitis" (IH) or "serum hepatitis" (SH) until the immunologic and other properties of the agent concerned have been demonstrated. When these properties are not known, reference to the disease as "viral hepatitis" might avoid the classification of a virus as one of "infectious hepatitis" (IH), when later it may prove to be one of the strains of "serum hepatitis virus" (SH). The existence of such confusion is evident from the experimentally demonstrated presence of both strains of virus in the blood, although the serum hepatitis virus (SH) has not been obtained from the commonly infective source of the infectious (epidemic) hepatitis virus (IH); i. e., the stool. The data of the present report, although not adding conclusive evidence for or against the antigenic differences already demonstrated, have pointed to an interesting difference between them in respect to the protective effect of gamma globulin.

These data have indicated not only a differing effect on serum hepatitis SH with different batches of gamma globulin, but also an interesting phenomenon in the field of viral diseases, namely, an apparent prolongation of the incubation period of serum hepatitis SH by the parenteral injection of certain batches of gamma globu-

lin, 10 cc., during this period. In contrast, in the studies to date on infectious (epidemic) hepatitis IH, such prolongation apparently has not been observed.

GAMMA GLOBULIN IN INFECTIOUS (EPIDEMIC) HEPATITIS (IH VIRUS)

The use of gamma globulin obtained from large pools of American Red Cross blood by means of the fractionation method developed by Cohn and his co-workers in the prevention of hepatitis IH has been previously described.³ In four epidemics of hepatitis IH in widely separated areas, gamma globulin in amounts of approximately 0.06 to 0.15 cc. per pound of body weight was effective in protecting a large proportion of exposed susceptible persons. In the first epidemic in which gamma globulin was used prophylactically, attenuation of the disease was observed in a number of persons who were not completely protected.^{3a} In these persons and in the few in whom unmodified hepatitis developed, despite previous injection of gamma globulin, no prolongation of the incubation period was apparent, although the evidence on this point was inconclusive because of the uncertainty of the exact time of exposure. However, if prolongation of the incubation period had occurred, a number of cases of hepatitis should have been noted in the treated group more than one week after the injection of the globulin. The paucity of such cases suggests that in this disease the globulin usually either prevented or attenuated the disease, without apparent prolongation of the incubation period.

Confirmatory evidence for such protection and attenuation, together with absence of prolongation of the incubation period, was obtained by Paul and Havens in a similar study.⁴ In this study also, the lack of cases occurring more than ten days after the injection of the globulin apparently indicated that the incubation period had not been lengthened by the parenteral injection of the globulin.

In the two epidemics of hepatitis IH in the Mediterranean Theater of Operations in which gamma globulin was used prophylactically, it was not possible to obtain data relative to attenuation of hepatitis or to prolongation of the incubation period.^{3b}

GAMMA GLOBULIN IN HEPATITIS SH

Field Studies.—The study of the effect of prophylactic gamma globulin on hepatitis SH (long incubation period) has been hampered by the lack of clearcut epidemics of the disease. The groups studied to date have been composed entirely of battle casualties who had received transfusions of blood or plasma in the various theaters of operation and then had been evacuated to general hospitals in the Zone of the Interior. That the hepatitis which occurred in these groups was, in almost all instances, hepatitis SH was indicated by the fact that in other battle casualties in the same hospitals who had not received blood products hepatitis rarely developed, and the incubation period apparently in all cases was more than sixty days. Studies have been reported in two different groups of such battle casualties in two widely separated United States Army general

From the Departments of Pediatrics and Medicine, School of Medicine of the University of Pennsylvania, Philadelphia, and The Children's Hospital of Philadelphia.

These investigations were conducted in part under the Commissions on Measles and Mumps, on Virus and Rickettsial Diseases, and on Liver Disease, Army Epidemiological Board, Preventive Medicine Service, Office of the Surgeon General, United States Army.

hospitals.⁵ In the first hospital, two doses of gamma globulin of 10 cc. each were injected at an interval of thirty days in alternate battle casualties who had received blood or plasma following injury. That the test and control groups were chosen by chance is indicated by the closely similar distribution of the battle casualties from the Mediterranean, European and Pacific theaters of operation in these two groups. In this controlled study excellent protection apparently was afforded against the hepatitis SH virus by the gamma globulin. However, in the second study, at the other hospital, in which a single dose of gamma globulin, 10 cc., was used, there was no significant difference in incidence of hepatitis SH noted between the test and control groups. Despite the lack of complete protection, the group data indicated that the single injection of gamma globulin had resulted in a prolongation of the mean incubation period. While the mean length of time between transfusion and injection of globulin in the test group was almost identical

ever, carefully collected data permitted a comparison between the mean incubation period of cases of hepatitis which preceded the routine use of globulin and the mean incubation period of cases which occurred after the routine single injections of gamma globulin were started. As the control period preceding the routine

† Intervals from transfusion to onset of hepatitis in 76 patients who had previously received transfusions and who subsequently had hepatitis. The mean interval for patients given globulin was one hundred and sixty-one days and the mean interval for patients not given globulin eighty-eight days.

with the mean length of time between transfusion and the day of designation as a control in the other (control) group, the succeeding mean intervals to the onset of hepatitis were different. In the test group the interval (fifty-two days) was over 50 per cent longer than the comparable interval (thirty-four days) in the controls. As the possibility was approximately 1 in 400 that such a prolongation was purely the result of chance, the observations suggest the presence of a virus-inhibiting factor in the batch of gamma globulin used, in spite of its lack of effect on the incidence of the disease.

As a result of the protective effect indicated by the decrease incidence of hepatitis SH in those given injections at the first hospital, all Army general hospitals in this country were directed to administer routinely, on admission, a single intramuscular injection of gamma globulin to all newly evacuated battle casualties that had received transfusions. For this reason, further comparative studies with casualties (not given injections) as controls were not possible. In one hospital, how-

use of gamma globulin was approximately five months in duration, whereas the study period following institution of the routine use of globulin was approximately seven months, the time intervals are not comparable. However, the case rate of hepatitis in battle casualties that had received transfusions in this hospital remained approximately the same throughout this twelve month period.⁶ Thus, the occurrence of 33 cases of hepatitis in the control group and of 43 cases in the group given injections within the five and seven month periods, respectively, would approximate the expected number if there were no decided change in the case rate. This suggested that the single dose of globulin, 10 cc., had not decreased the incidence of hepatitis SH. That 3 deaths occurred in the 33 control casualties, whereas no deaths occurred in the groups given injections, is of interest, although not statistically significant. Although ineffective in decreasing the incidence, a highly significant difference was observed between the mean incubation period (eighty-eight days) in casualties not treated with gamma globulin and the mean incubation period (one hundred and sixty-one days) in the casualties treated with gamma globulin. These data are presented in table 1. As in the second

hospital previously mentioned, the observations in this third hospital also strongly suggested some inhibitory effect of the batch of globulin used on the virus of hepatitis SH.

F.; Nicholson, J. T., and Edgar, A.: An Evaluation of Immune Serum Globulin as a Prophylactic Agent Against Homologous Serum Hepatitis, Am. J. Med. Sc. 213: 53 (Jan.) 1947.

6. Personal communication to the authors from Major William A. Jeffers, Medical Corps, Army of the United States, Chief of Medical Service, McGuire General Hospital, Richmond, Va. The incubation periods were calculated from the date of injury, although plasma or blood, injected also on subsequent dates, might have been responsible for the hepatitis. Such errors should have occurred with approximately equal frequency in the control and treated groups and, thus, would not alter essentially the evidence obtained of decided differences between the groups.

GAMMA GLOBULIN IN EXPERIMENTALLY INDUCED HEPATITIS SH

Studies were carried out to determine the possible protective effect of gamma globulin against the hepatitis virus SH^{1, 2} in volunteers.

In the first study, 5 volunteers each received parenteral injections of a mixture composed of 2 cc. of icterogenic plasma (virus SH) and 1 cc. of human immune serum (gamma) globulin. In 3 of these volunteers hepatitis developed, in 2 with jaundice and in 1 without jaundice. Five other volunteers simultaneously received, at separate sites of injection, 2 cc. of the icterogenic plasma and 10 cc. of the gamma globulin preparation. In 2 of these volunteers hepatitis

developed, in 1 with jaundice and in 1 without jaundice. Of 4 control volunteers who received parenterally the icterogenic plasma alone, in 2 hepatitis with jaundice developed. The results are summarized in table 2. No significant differences in the lengths of the incubation periods were observed in the cases in these different groups, the interval between injection and the onset of hepatitis being three to three and a half months in all.

evidence of hepatitis. Seven volunteers served as controls. Each received intramuscularly 3 cc. of icterogenic plasma. In 2 of these volunteers mild hepatitis developed without jaundice, and 2 had questionable hepatitis. The results are summarized in table 3. Since only mild hepatitis without jaundice was produced in the group of controls, it seemed probable that the viral agent had become attenuated. Therefore, the apparent protection afforded by three 10 cc. doses of gamma globulin against this attenuated agent must be regarded as inconclusive. On the other hand, the preparation of gamma globulin used failed to neutralize the attenuated viral agent. This is indicated by a similar incidence and similar incubation period of mild hepatitis in the group receiving the neutralization mixture and in the group of controls.

The third study was similar to the second. The same strain of hepatitis virus SH was used, but the material represented the second human passage virus SH (Fort Bragg strain). Seven volunteers were each given intramuscular injections of a mixture composed of 1 cc. of icterogenic serum and 20 cc. of gamma globulin. In 2 of the volunteers hepatitis developed with jaundice, and in 1 hepatitis developed without jaundice. Seven other volunteers simultaneously received by intramuscular injection 1 cc. of the icterogenic serum, followed by an injection of gamma globulin, 0.06 cc. per pound of body weight, after one, two and three months, respectively. In 2 of the volunteers hepatitis with jaundice developed; 1 had hepatitis without jaundice, and 1 had questionable hepatitis. Seven volunteers served as controls. Each received intramuscularly 1 cc. of icterogenic serum. In 1 of the volunteers hepatitis developed with jaundice; 1 had hepatitis without jaundice, and 2 had questionable hepatitis. The results are summarized in table 4. Gamma globulin afforded no protection either when mixed with virus SH previous to injection or in

TABLE 5.—Effect of Convalescent Plasma on Hepatitis Virus SH

Group	Material and Amount	Number Inoculated	Results			Incubation (Days)
			Hepatitis With Jaundice	Hepatitis Without Jaundice	Percentage of Hepatitis

Control.....	10 cc. convalescent plasma	4	0	0	0.0	..

The clinical study in one of the United States Army general hospitals already mentioned indicated a significant decrease in the incidence of hepatitis SH among the group of battle casualties receiving two doses of gamma globulin of 10 cc. each at an interval of thirty days. The second and third studies were carried out to ascertain the value of three prophylactic doses of gamma globulin against hepatitis virus SH and to study further the neutralizing effect of gamma globulin on this virus.

In the second study, 7 volunteers were each given intramuscular injections of a mixture composed of 3 cc. of icterogenic plasma and 10 cc. of gamma globulin. In 1 of these volunteers mild hepatitis developed without jaundice, and 2 had questionable hepatitis. Each of 7 other volunteers simultaneously received by injection 3 cc. of icterogenic plasma, followed by 10 cc. of gamma globulin after one, two and three months, respectively. None of these volunteers showed any

mild hepatitis. The results are summarized in table 3. No significant differences in the length of the incubation period was observed in these different groups.

CONVALESCENT PLASMA IN EXPERIMENTALLY INDUCED HEPATITIS SH

Study No. 4.—A study was carried out of the possible protective effect of hepatitis convalescent plasma against hepatitis virus SH. The same icterogenic serum (Fort Bragg virus, second passage) used in the last gamma globulin study was employed. The convalescent plasma was obtained from a single case of hepatitis SH with jaundice two and one-half months after recovery.

Four volunteers were each given intramuscular injections of a mixture composed of 2 cc. of icterogenic serum and 10 cc. of convalescent plasma, followed by 20 cc. of convalescent plasma after one, two and three months, respectively. In 1 of the volunteers hepatitis

with jaundice developed. In order to determine whether or not the convalescent plasma contained hepatitis virus SH, 4 volunteers were given parenteral injections of the convalescent plasma alone. None showed evidence of hepatitis. The results are summarized in table 5. In this study, which was too limited for conclusive evidence, convalescent plasma from a single person apparently failed to protect against hepatitis virus SH, suggesting that neutralizing antibodies were either absent or not present in sufficient concentration to afford protection.

COMMENT

The significance of the aforementioned observations may be reviewed in the light of the following considerations:

1. *The Possible Inhibiting Effect of Gamma Globulin on Different Strains of Hepatitis Virus.*—There can be little question that various batches of gamma globulin prepared from pools of plasma from two to three thousand donors, collected during World War II by the American Red Cross, have had a decidedly inhibiting effect on the virus of the infectious (epidemic) hepatitis IH, in view of the protective results obtained in the four widely separated epidemics mentioned. Although no direct neutralization studies utilizing the globulin and strains of this virus have been carried out, it appears highly probable that the resistance of the human host results from the passive transfer of protective antibodies in the gamma globulin. Despite the lack of measurement of such antibodies, it also appears probable, inasmuch as various batches of globulin have been effective, that a fairly uniform titer of such antibodies has been present. Such uniformity would be entirely similar to the fairly uniform titers in gamma globulin of other virus antibodies, such as those of human influenza viruses A and B and of swine influenza virus. If present, such general uniformity could accord with a wide prevalence of infectious hepatitis IH in an apparent (clinical) or in an inapparent (subclinical) form. The epidemiologic studies of this disease, particularly as related to the frequency of the virus in the stools, could well explain its wide prevalence in the general population in the apparent or inapparent forms, with a resulting antibody production.

The field observations on serum hepatitis SH have included studies in three widely separated general hospitals in which large amounts and different batches of gamma globulin were used. In all three studies, the gamma globulin appeared to have an inhibiting effect on the virus. The effect was protective, however, only in the study in which two doses of 10 cc. each were used.

In the studies on volunteers, it is possible that the strain of virus was different from that (or those) encountered in the battle casualties. Differences in the quantity or composition of the gamma globulin preparations also may account for the lack of protection, since it is possible that hepatitis virus SH is not as widespread as virus IH or does not produce sufficient neutralizing antibodies to be protective even when concentrated. The fractionation process or storage of gamma globulin may have diminished or destroyed antibodies present in the original plasma, although in all batches used satisfactory titers of antibodies against influenza A and B viruses were observed. (For influ-

enza A virus, the PR 8 strain was used; for influenza B virus, the Lee strain was used.)

In the study with volunteers in which a neutralization test was carried out with hepatitis SH convalescent plasma, and multiple prophylactic doses of convalescent plasma were subsequently injected, virus-neutralizing antibodies could not be demonstrated. This convalescent plasma was taken from one patient having hepatitis with jaundice as a result of inoculation with the same strain of hepatitis virus SH used in this study. Because of the small size of the group, no conclusions can be drawn.

Despite the many problems which remain unanswered, these studies seem to afford some additional evidence for antigenic differences between hepatitis viruses SH (Fort Bragg strain) and the epidemic IH strains previously studied. The final solution of this problem and the evaluation of the role of gamma globulin in the prophylaxis of serum hepatitis obviously will require further studies in volunteers or, should they become available, in susceptible animals.

As little is known of the epidemiologic aspects of serum virus SH hepatitis, which may possibly be different from that of infectious (epidemic) hepatitis, a hypothetical discussion concerning the incidence of apparent or inapparent cases is not appropriate. Certain evidence suggests that human carrier states may exist wherein the virus of serum hepatitis is present either continuously or from time to time in the blood stream, in such form as to infect recipients of whole blood or plasma from donors who may act as "carriers." In what manner gamma globulin from large pools of plasma could acquire virus-inhibiting properties against such a virus agent is highly speculative and beyond the scope of this discussion.

2. *The Possible Presence of Active Serum Hepatitis Virus in Gamma Globulin.*—The question arose as to whether the recorded delay in the incubation period of serum hepatitis in the hospitals studied did not result from the presence of the active serum hepatitis virus in the injected gamma globulin. If present and active, this could have caused a later increase of serum hepatitis in the groups given injections and, in the case of the last hospital, could partly have accounted for the exceptional length of the mean incubation period in the group given injections. That the presence of active virus in the gamma globulin would not explain the recorded observations appears clear for the following reasons: (a) At the first hospital, the two doses of globulin, given one month apart, apparently afforded a high degree of protection, and cases of hepatitis in the test group did not continue to appear, as should have been the case if the gamma globulin had been infective. (b) At the second hospital, the incidences of hepatitis in the test and control groups, chosen alternately, were not significantly different. The test group should have shown a significantly higher incidence of hepatitis, rather than merely a prolonged mean incubation period, if the gamma globulin itself had been infective. (c) At the third hospital, although it lacked the alternation of choice of test and control groups, the similar incidence of hepatitis both preceding and following the use of gamma globulin indicated that the globulin itself had not been infective. (d) Finally, serum hepatitis has not been observed in children given injections of gamma globulin for prophylaxis against other diseases. In studies on measles, approxi-

mately 3,000 children thus treated have been followed up carefully, with complete absence of any evidence that active serum hepatitis virus was present in the gamma globulin used. The absence of hepatitis in so large a number of the susceptible subjects (children) that received injections appears highly significant.⁷

Enders⁸ has observed that when mouse encephalomyelitis virus (Theiler's virus) and tobacco mosaic virus were added to pools of plasma in which no antibodies to these viruses were present, the gamma globulin fractions, as well as all other fractions of the plasma obtained by the method of Cohn and his co-workers, still contained the active viruses. The strains of virus of serum hepatitis thus far studied appear to be comparatively resistant to heat and to other treatment, so that the process of fractionation presumably should not inactivate them if they behaved in a manner at all similar to that of the other two viruses mentioned. The apparent absence of active serum hepatitis virus from the gamma globulin fractions thus far studied may result from inhibiting or neutralizing factors present at times in the large pools of plasma of the American Red Cross, from which the gamma globulin used in these studies was derived. It is also possible that the concentration of such inhibiting or neutralizing factors in the gamma globulin may add to both the safety and effectiveness of such materials. It seems possible that a few persons with extremely high titers of antibodies to the virus of serum hepatitis may furnish a protective titer for the entire pool and, in particular, for certain batches of the gamma globulin derived from such pools.

However, cases of hepatitis reported to the American Red Cross⁹ among persons receiving fraction I (fibrinogen and antihemophilic globulins) indicate the frequent presence of virus SH in this fraction. Its apparent absence from the gamma globulin of fractions II and III and the absence of virus SH antibodies from many batches studied of these same fractions necessitate consideration of the following possibilities.

1. The virus SH may differ from the animal and plant viruses studied by Enders⁸ in its distribution among the fractions and may be concentrated in fraction I, possibly as the result of affinity for certain proteins.

2. The virus SH may form complexes with proteins in fractions II and III, which are filtered out or lost during processing.

3. The virus SH may be inactivated under the conditions of storage and handling of gamma globulin which have been more rigorous than those employed for fraction I.

The dilution factor discussed by Andrewes¹⁰ in its possible relation to the occurrence of serum hepatitis cannot as yet be fully evaluated. It is thus clear that many of the problems here discussed concerning the epidemiologic study and control of serum hepatitis require additional basic data before conclusive answers to them can be found.

7. Three cases of supposedly long incubation hepatitis following gamma globulin therapy have been mentioned personally to the authors. All of these could possibly have been chance infections with the IH virus. The paucity of such occurrences, when compared with the relatively high incidence (5 to 7 per cent) following treatment with pooled plasma from which the gamma globulin was prepared, strongly suggests that the gamma globulin was not in itself responsible for such hepatitis.

3. *The Possible Mode of Action of Gamma Globulin as Related to the Incubation Period of Serum Hepatitis.*—Inasmuch as the evidence obtained from the three studies in the general hospitals suggests the presence of inhibiting factors in certain batches of gamma globulin against the serum hepatitis virus, it is of particular interest to consider the possible manner in which the injection of a single dose, 10 cc., of gamma globulin may prolong the incubation period. A moderate amount of clinical evidence indicates that convalescent mumps plasma, given in sufficient quantities parenterally, at times will lengthen the incubation period of this disease but will rarely protect completely the exposed susceptible person. Such behavior appears to be rare in viral diseases. In serum hepatitis, the length of the incubation period may indicate a balanced relation between parasite and host which lends itself to effective inhibition or lengthening of the incubation period of the parasite by a relatively small amount of inhibiting factor. The effect of the gamma globulin may be based on a purely quantitative relation between the number of viral bodies and the amount of inhibiting factor in the gamma globulin. Thus, two doses of 10 cc. given at a thirty day interval, or 20 cc. in all, may be sufficient to neutralize all of the virus particles present, whereas one dose, 10 cc., may reduce the amount of virus to a point from which the relatively slow process of multiplication is repeated. Thus, the prolongation of the incubation period may be solely the result of delay in the parasite's increase of virus particles to a point at which clinical disease can be developed.

On the other hand, the protective effect of the two doses of gamma globulin may have resulted from the fact that the second injection of antibodies had occurred at a more vulnerable step in the life cycle of the parasite, possibly when it was present in the blood stream and before extensive cellular invasion had occurred. In lieu of further evidence, it would appear that the first and simpler hypothesis is the more tenable.

SUMMARY AND CONCLUSIONS

Gamma globulin from large pools of human plasma apparently contains protective factors against strains of infectious (epidemic) hepatitis IH virus of shorter incubation (approximately eighteen to forty days). Gamma globulin also has shown decided differences in its protective properties against strains of serum hepatitis SH virus of longer incubation (approximately sixty to one hundred and fifty days). In the infectious (epidemic) hepatitis IH, the protective effect has been conclusively demonstrated. In serum hepatitis SH at one general hospital for battle casualties, two injections of gamma globulin, 10 cc. each, given at a thirty day interval during the incubation period of the disease, were highly protective. In two other general hospitals, in which a single injection of gamma globulin (10 cc.) was administered during the incubation period, decided prolongation of the mean incubation periods resulted in the two test groups of battle casualties. In these two hospitals, the gamma globulin apparently did not alter the incidence of hepatitis SH in the test groups, despite its prolongation of the mean incubation periods. Four deaths occurred in the control groups and none in the groups given injections in these two hospitals.

In contrast to serum hepatitis SH, prolongation of the incubation period as the result of previous injection of gamma globulin has not been observed in infectious (epidemic) hepatitis IH, the effect being one of protection or attenuation.

In a group of studies in volunteers, the batches of gamma globulin tested apparently did not contain virus-neutralizing or inhibiting factors effective against the strain of serum hepatitis SH virus used. In a single small study, hepatitis convalescent plasma from one subject failed to afford inhibiting factors against the same strain of serum hepatitis SH virus.

It appears possible that the process of fractionation itself may concentrate the virus in fractions other than the gamma globulin or that the manipulations of filtering and storage may eliminate the virus, while in certain batches of gamma globulin protective antibodies may be an added factor in preventing contamination of the gamma globulin with virus SH.

NOTE.—It was found impossible to trace each source of plasma for the gamma globulin used in these studies. Gamma globulin for the volunteer studies consisted of material derived from more than one biologic firm and from several areas of the United States. It included both fraction II and III-1 gamma globulin, in the proportions they are obtained in the most recent method developed by Oncley and his associates for the subfractionation of II and III. These were lots number 14, 28-4, 33-1, 68-2 and 68-3.

METHODS OF PROTECTION AGAINST HOMOLOGOUS SERUM HEPATITIS

II. The Inactivation of Hepatitis Virus SH with Ultraviolet Rays

Philadelphia

Much attention has been focused on the transmission of the causative agent of homologous serum hepatitis by the parenteral administration of blood and blood products. A number of conclusive experimental studies have shown that plasma and serum may harbor the responsible viral agent.¹ During the recent war, in many battle casualties who had received transfusions of whole blood or plasma, or both, subsequently, within periods of two to five months, homologous serum hepatitis developed.² Since the end of the war and the release of large stores of dried pooled plasma for civilian use in this country, a significantly high incidence of serum hepatitis has been reported resulting from transfusions with this and other plasma.³ Reports from England

by Spurling, Shone and Vaughan⁴ also indicate an incidence of 7.3 per cent homologous serum jaundice among 1,054 patients receiving pooled serum and plasma. Inasmuch as laboratory methods for the detection of ieterogenic agents in blood and blood products have not been perfected, the prevention of homologous serum hepatitis has offered a challenge to investigators in the field of preventive medicine.

Methods of control of homologous serum hepatitis, thus far, have been inadequate. Careful selection of donors has been helpful. However, this latter method does not exclude those persons who might have had inapparent infections and possibly remained as carriers and those persons whose blood might be obtained during the long incubation period of the disease.

A means for inactivating hepatitis virus SH^{1b} in serum albumin by prolonged heating has been demonstrated.⁵ This method, however, is not applicable to whole blood, plasma or serum. Recent experimental studies have shown human immune (gamma) globulin to be unreliable in providing protective antibodies.⁶

The inactivation of other viruses by exposure to ultraviolet rays has been successfully employed by many investigators. The Oppenheimer-Levinson apparatus⁷ and the Habel-Sockrider apparatus,⁸ both utilizing the general principle of irradiating continuously flowing thin films of virus suspensions, have demonstrated the usefulness of these methods under certain conditions.

The possibility of inactivating hepatitis virus SH in plasma and serum has been investigated to a limited extent, but, thus far, the results of these studies have been conflicting. In this country, the work of Oliphant suggested that hepatitis virus SH in serum could be inactivated with ultraviolet rays.⁹ However, in his series of studies, there was wide variation in the amounts of radiant energy used. Also, the effect of irradiation on the serum proteins apparently was not fully determined. In England, MacCallum and his co-workers carried out similar studies.¹⁰ Results contrary to those of Oliphant were obtained, inasmuch as the supposedly suitable exposure failed to inactivate the viral agent. Where greater exposure was used, gross changes in the serum proteins were noted in electrophoretic studies.

The recent work of Wolf and his co-workers, with the Oppenheimer-Levinson apparatus, suggested that plasma may be irradiated without significant alteration of the proteins and safely administered to patients.¹¹ Their work did not involve the use of hepatitis viral agents.

The purpose of this paper is to present experimental evidence indicating that hepatitis virus SH (homologous

serum jaundice) can be inactivated with ultraviolet rays and that such inactivation may be accomplished by a safe and practical procedure.

METHODS AND MATERIALS

Source and Nature of Materials.—The icterogenic material used in this study represented a pool of serum specimens collected from volunteers during the early stages of induced homologous serum hepatitis. This serum had been continuously frozen at -20°C . for a period of two and one-half years. The strain of virus SH contained in this serum has been described in previous reports.^{1a} One lot of this serum pool, when used six months prior to the present study, produced hepatitis in approximately 50 per cent of the inoculated volunteers.⁵

Volunteers.—Healthy adult male volunteers were used in this study. Preliminary data prior to their inoculation have been dealt with in a previous report.^{1a} Preinoculation hepatic studies were performed on each volunteer to rule out the possibility of asymptomatic hepatic disease and to establish for each subject a range of normal values for the various hepatic tests.

Ultraviolet Apparatus.—A Habel-Sockrider type of apparatus was used for processing the icterogenic serum.⁸ This apparatus consisted of a rotating glass tube, 52 cm. in length and 2.53 cm. in diameter. An 18 watt cold quartz lamp¹² passed lengthwise through the center of the glass tube. This lamp has an intensity of about 3,500 microwatts per square centimeter at a distance of 9 mm., which was the distance from the burner to the surface of the serum irradiated in the rotating tube. Approx-

Postinoculation Follow-Up.—Tests of hepatic function were performed on all volunteers every seven to ten days for the first two months after inoculation and once to twice weekly thereafter. Examinations of urine for bilirubin and urobilinogen were performed on each volunteer two to four times weekly. The tests of hepatic function included the total serum bilirubin and one minute direct-reacting serum bilirubin, sulfobromophthalein sodium, cephalin cholesterol flocculation, serum colloidal gold and colloidal red flocculation, thymol turbidity and flocculation, urine bilirubin and urine urobilinogen tests. Visible scleral jaundice is usually present when total serum bilirubin values are greater than 1.4 mg. per hundred cubic centimeters.

RESULTS

The results are given in the table. Of 11 volunteers in the group of controls who received 4 cc. of non-irradiated icterogenic serum intramuscularly, in 2 hepatitis with jaundice developed after incubation periods of seventy-seven and eighty days. One volunteer had hepatitis without jaundice after an incubation period of eighty-seven days. Three volunteers after incubation periods of seventy-three to eighty days showed signs and symptoms compatible with the diagnosis of mild hepatitis without jaundice. The duration of symptoms and signs in these 3 was seven to twenty-one days. They exhibited malaise, lassitude, anorexia, nausea, occasional vomiting, discomfort in the right upper

Effect of Ultraviolet Rays on Hepatitis Virus SH

mately 85 per cent of its radiation is given off in the 2,537 angstrom unit wavelength. The glass tube could be rotated at varying speeds. For the present experiment 240 revolutions per minute were used, with the glass tube at an angle of 12 degrees from the horizontal.

Procedure.—The icterogenic serum was thawed and then screened through sterile 200 mesh silk to remove flocculent material. The serum was delivered from a separatory funnel to the side of the rotating tube at a constant rate of flow controlled by a flow meter. The rate of flow was 24 cc. per minute, and the time of exposure was 10 seconds. The average thickness of the film of serum was calculated to be 0.263 mm. Turbulence produced by rotation resulted in a similar exposure to irradiation of all parts of the serum.

Inoculations.—A group of 15 volunteers served as controls and received portions of the same icterogenic serum without irradiation by intramuscular injection. Of this group of 15, 11 volunteers each received 4 cc. of icterogenic nonirradiated serum. Of the remaining 4 volunteers, each received a mixture composed of 2 cc. of icterogenic nonirradiated serum and 10 cc. of plasma from 1 subject, convalescent two and a half months. Each subject also received 20 cc. of the same convalescent plasma after one, two and three months, respectively. This latter group of 4 was controlled by a second group of 4 volunteers, each of whom received 10 cc. of the same convalescent plasma in a single dose. This latter group was arranged for the purpose of determining whether the convalescent plasma harbored active hepatitis virus SH.

Eleven additional volunteers served as the test group to determine the effect of irradiation. Each was given 7 cc. of irradiated icterogenic serum by intramuscular injection. No untoward reaction was observed following inoculation.

abdominal region and right upper quadrant tenderness, particularly noted in the right epigastrium. No significant change in the position of the liver edge was noted. At no other time during the period of observation were similar episodes encountered. None of these 3 volunteers had positive reactions to tests of hepatic function during or following their mild clinical illnesses. The observations did not suggest any other disease process. It was felt that, in view of the incubation period and the nature of the signs and symptoms, one would be justified in classifying the disease in these 3 cases as presumptive hepatitis. Similar observations have been made previously.¹³

Of 4 volunteers in the group of controls who had received a mixture of 2 cc. of nonirradiated icterogenic serum and 10 cc. of convalescent plasma, plus 20 cc. of convalescent plasma after 1, 2 and 3 months, in 1 hepatitis with jaundice developed after an incubation period of ninety-three days. None of the 4 volunteers who received 10 cc. of convalescent plasma alone and served as controls to the aforementioned group showed any evidence of hepatitis.

The incidence of hepatitis in the group of 15 controls, therefore, was 47 per cent, if one includes the 3 cases of presumptive hepatitis. If the 3 subjects with presumptive hepatitis are excluded, the incidence of 4

13. Neefe, J. R.; Stokes, J., Jr.; Garber, R. S., and Gellis, S. S.: Studies on the Relationship of the Hepatitis Virus to Persistent Symptomatic, Disability, and Hepatic Disturbance ("Chronic Hepatitis Syndrome") Following Acute Infectious Hepatitis, *J. Clin. Investigation* 26: 329 (March) 1947.

undoubted cases of hepatitis in 15 volunteers is 27 per cent. The maximum total serum bilirubin values in the 3 controls with jaundice were 7.9, 1.6 and 3.1 mg. per hundred cubic centimeters.

Of the group of 11 volunteers, each of whom received 7 cc. of irradiated serum intramuscularly, none showed the slightest clinical or laboratory evidence of hepatitis during an observation period of five months. It should be noted that the dosage used, 7 cc., was almost double that used for the controls.

It was deemed advisable to determine whether allergy had developed in the volunteers who received the irradiated serum as a result of any altered protein that might have been present. Preliminary electrophoretic and biochemical studies of plasma similarly exposed to ultraviolet rays had demonstrated no alterations in the plasma proteins except for slight reduction in prothrombin and complement. It was necessary, therefore, to determine by clinical trial whether or not subsequent injections of irradiated plasma might give rise to allergic manifestations, because of sensitization resulting from any minimal protein changes.

Irradiated normal plasma which had received the same exposure as the icterogenic serum was injected intradermally, intramuscularly and intravenously in amounts of 0.1 cc., 1.0 cc. and 10.0 cc., respectively, in a group of 5 volunteers who had originally received irradiated serum. In addition, the same tests were carried out on an equal number of controls. No allergic response or untoward reaction was noted following these tests. Five additional volunteers who had originally received the irradiated serum were then tested for sensitivity with larger injections of irradiated plasma. Each was given 10 cc. of irradiated plasma intravenously. No untoward response was observed during a forty-five minute period of observation. Each was then given an intravenous injection with amounts of irradiated plasma ranging from 75 to 150 cc. There was no immediate or delayed reaction, and their temperatures remained normal. Clinical sensitivity studies, therefore, seemed to substantiate the lack of important electrophoretic and biochemical alterations in the irradiated plasma.

COMMENT

The incidence of hepatitis in the groups of controls, including the 3 cases of presumptive hepatitis, was 47 per cent as compared to 0 per cent in the test group that received irradiated serum. Whether or not the 3 presumptive cases are included, these results are significant.

One of the principal factors involved in the amount of exposure that any given material receives in the apparatus for irradiation, previously described, is the rate of flow of that material through the apparatus. Hampil and her co-workers¹⁴ have shown that neurotropic viruses in general, with the exception of rabies virus, are more resistant and require a slower rate of flow for inactivation than a number of other viruses. Since hepatitis virus SH has been shown to be unusually resistant to various physical and chemical agents, it was felt that the infective serum should be exposed to irradiation within the rate of flow range employed for inactivation of certain neurotropic viruses previously tested.

Another important factor was the possible alteration of serum proteins by irradiation. With the method employed, the earliest detectable protein changes are found with a rate of flow of 16 cc. per minute. The

rate of flow in this study was 24 cc. per minute. Chemical fractionation and electrophoretic studies of normal human plasma irradiated at the same rate of flow as the icterogenic serum revealed no alteration of proteins except for a slight decrease in prothrombin and complement. In the relatively small number of cases studied, no allergic manifestations developed in members of the test group when later studied for acquired sensitivity by intradermal, intramuscular and intravenous injections of irradiated normal plasma.

Since there are no laboratory methods for the detection of virus SH in plasma and serum, it is apparent that inadvertent administration of icterogenic blood products cannot be avoided unless certain measures, such as carefully controlled routine exposure to ultraviolet rays of human plasma and serum, would render them safe for administration.

Oliphant²⁰ pointed out that the factors of titer of the icterogenic agent and the dose of serum given could possibly have an influence on the "icterogenic capacity" of irradiated material. Both in his experiments and in the present one, there was no possibility of determining the importance of these factors.

The preparation of virus vaccines by exposure to ultraviolet rays of suspensions of virus suggests the possibility of producing a vaccine for homologous serum hepatitis using known icterogenic materials. Whether or not hepatitis virus SH retains its antigenic properties following inactivation is not known. The resistance of the subjects inoculated with irradiated serum will be tested later. With no method of estimating the concentration of virus SH in a given amount of serum or plasma and no method of concentrating the virus, one might find it difficult to produce a reliable method for immunization.

SUMMARY AND CONCLUSIONS

A practical, safe and effective method for irradiating icterogenic serum and plasma is presented. Of 15 volunteers who received nonirradiated icterogenic serum, in 3 hepatitis with jaundice developed, in 1 hepatitis developed without jaundice and 3 had presumptive hepatitis. Of 11 volunteers who received irradiated icterogenic serum, none showed any evidence of hepatitis. Similarly irradiated plasma revealed no alteration of the electrophoretic pattern. By chemical fractionation methods, the plasma proteins were essentially normal. There was a slight decrease in prothrombin and complement. The initial inoculation of 11 volunteers with irradiated serum produced no untoward reaction. Subsequent inoculation of 10 of these volunteers with irradiated plasma intradermally, intramuscularly and intravenously, revealed no evidence of acquired sensitivity. This clearcut result strongly favors the routine use of exposure to ultraviolet rays of serum and plasma under properly standardized conditions.

Cost of Radioactive Materials.—Use of the facilities and by-products of the reactor at Oak Ridge has increased tremendously the supply of radioactive materials, progressively reduced their costs to qualified research agencies, and brought many of the rarer substances within reach of the ordinary technician. A report issued by the United States Commission on the completion of the first year of the isotope program gave examples. One millicurie of carbon 14, if produced by using a cyclotron, would cost approximately \$1,000,000; the same amount manufactured in the atomic piles of Oak Ridge is being sold at \$50. —The Department of State publication 3161, General Foreign Policy Series 3, released June 1948.

INHALATION OF PENICILLIN DUST

LOUIS KRASNO, M.D., Ph.D.

MARY KARP, M.D.

and

PAUL S. RHODES, M.D.

Chicago

The preliminary results obtained with the inhalation of penicillin dust indicate that this is an effective and practical method in the treatment of many types of infections of the respiratory tract.¹ The present report is a more extensive study of this procedure carried out on 357 patients from October, 1946.² In this study more inclusive information has been obtained on the following aspects of the problem: the incidence and nature of allergic reactions occurring with the method, an evaluation of the efficiency of this method in a large number of patients, particularly those with bronchiectasis, and a further refinement of the method to increase its practicality for home, office and hospital use.

APPARATUS

The apparatus devised for this purpose delivers a fine nonirritating penicillin dust to the respiratory tract. It is simple mechanically and therefore lends itself to immediate use, when such treatment is indicated, in the hospital, office or home.

The original device consists of an oronasal face piece, which is held on the face by an elastic head band (fig. 1). The front of the mask contains a large exhalation valve (A) in direct line with the stream of exhaled air. The portion of the mask beneath the chin contains a rubber sleeve (C) fitted with an inhalation valve (B) which directs the inhaled air in a plane at right angles to the stream of exhaled air. The inhalation valve is fitted with a detachable metal chamber (D) containing the penicillin dust. The chamber is fitted with a fine rayon wire mesh platform (E), on which the penicillin dust is placed. During inhalation, the air is drawn through this platform and lifts the penicillin dust through the inhalation valve into the airways. The penicillin dust is protected against exhaled moisture by the one way inhalation valve and the arrangement by which the exhaled air is released in the plane at right angles to the inhaled air. There is a hole in the top of the mask about 6 mm. in diameter. This additional air inlet avoids any feeling of resistance on inspiration and is necessary in order to keep the amount of inhaled penicillin dust at optimum quantities. The penicillin dust used in this study was crystalline sodium penicillin G, processed to no. 50 to 100 mesh particles.³

Recently a modification of this apparatus was constructed (figs. 2, 3 and 4) to deliver penicillin dust more thoroughly throughout the respiratory tract.⁴ This device consists of a molded plastic discharge chamber, a detachable mouth piece and an alternate molded nose piece. The penicillin dust is contained in a small plastic cartridge, the bottom of which is fitted with a fine mesh wire screen, through which the penicillin dust

is released. The upper rim of the cartridge exhibits two small flanges, which fit into a groove and allow locking the cartridge in position in the discharge chamber. The distal end of the discharge chamber is formed into a curved tube runway containing an aluminum ball. On inhalation the aluminum ball is rapidly drawn up the runway until it strikes the cartridge containing the penicillin; the impact causes a release of a small amount of the penicillin dust into the discharge chamber. The upper end of the runway is grooved, so that the air to be inspired can by-pass the aluminum ball after it strikes the cartridge; the air to be inspired, as it by-passes the ball, carries the released penicillin dust directly into the respiratory passages. Thus, with each respiration a small but uniform amount of dust enters the respiratory passages until the total dose has been consumed; this is usually accomplished within three to five minutes. This is an advantage over the original device, which did not control the amount of dust per inhalation. Expiration is effected by breathing around the inhaler, through the nose if the mouth piece is used, through the mouth if the nose piece is used or by removing the inhaler from the mouth during expiration.

Fig. 1.—Oronasal mask for inhalation.

By omitting the valve mechanism for exhalation, it has been possible to reduce the loss of drug adhering to the apparatus surfaces to 10 per cent, as determined by assaying the penicillin content remaining in the inhaler after treatment is completed. This obviates one of the disadvantages of the mask used in the original work, as the mask has a larger surface to which penicillin may adhere.

PROCEDURE

Twenty normal subjects (including the authors) were used as an experimental group to determine any untoward effects of inhaling penicillin dust. This group was also used to establish penicillin blood level curves. Three hundred and fifty-seven patients with various types of infections of the upper and lower parts of the respiratory tract (table 1) were treated by this method; 174 were hospitalized and 183 were ambulatory. All hospitalized patients received 100,000 units of penicillin dust three times a day. Inhalations were continued until all the dust was inhaled, usually three to six minutes. Patients were instructed to refrain from eating or drinking for one hour following the treatment, to avoid washing down the penicillin dust from the

2. Since this paper was written there have been 160 additional cases, making a total of 517 patients treated with the inhalation of penicillin dust.

3. The penicillin for this study was processed by and furnished by the Abbott Laboratories, North Chicago, Ill.

4. This device for the inhalation of penicillin dust was originally developed by the Abbott Laboratories. The authors cooperated by offering suggestions for improvements on the original model.

posterior pharyngeal wall. The bronchiectatic patients received 100,000 units of penicillin dust three times a day for seven to ten days in the hospital, and the same regimen was continued for another week at home. During the third week 100,000 units of penicillin dust were inhaled one to two times a day, depending on the

Fig. 2.—A, mouth inhaler disassembled. B, sagittal section of mouth inhaler assembled.

requirements. There was gradual reduction in the number of treatments per week until the optimum number of treatments per week needed for maintenance of comfort was determined. Ambulatory patients received 100,000 units of penicillin dust one to three times a day, depending on the particular condition involved. Ambulatory bronchiectatic patients received one daily treatment at the office and two treatments at home for ten days. Thereafter the regimen followed was similar to that of hospitalized patients. Throat and nose cultures prior to first treatment and after last inhalation were made for all hospitalized patients. In the first 68 patients treated with this method, daily nose and

Fig. 3.—Mouth inhaler assembled (without penicillin cartridge) (A) and molded detachable nose piece (B).

throat cultures were obtained. Bacteriologic examinations of sputum were done when specimens were obtainable. The clinical progress of the patient was followed by the report of the patient, his physician and the authors. The duration of treatment for each subject was determined bacteriologically and by the clinical progress made. Approximately two thirds of the subjects had less than three treatments. The highest

number was reserved for the patients with chronic bronchitis, chronic sinusitis, bronchiectasis and bronchial asthma. It was not practical to obtain laboratory data for some of the ambulatory patients. However, this group gave added information regarding the clinical progress and allergic aspects of this type of treatment.

At the present time experiments are being conducted with streptomycin dust. One third of a gram of streptomycin and 100,000 units of penicillin are given three times a day. Experimental work is also being done on the distribution of the penicillin dust particles in the respiratory tract. The data obtained will be presented in a subsequent report.

RESULTS

The clinical conditions treated are tabulated in table 1. Two hundred and thirty-nine subjects (67 per cent) presented infections of the upper part of the respiratory tract, 169 of whom had symptoms of the "common cold." One hundred and ten patients (30 per cent) had infections of the lower part of the respiratory tract. Eight patients received penicillin dust as prophylaxis in the preoperative and postoperative management of surgical interventions.

Fig. 4.—Cartridges boxed and ready for use. Each cartridge contains 100,000 units of penicillin.

Tables 2, 3 and 4 present bacteriologic data⁵ obtained from throat, nose and sputum cultures prior to and following completion of the course of inhalation therapy.

5. These charts represent bacteriologic data based on the first 39 hospitalized patients treated. The bacteriologic results obtained in the remaining hospitalized patients were essentially the same.

There was a decided reduction in the number of, or complete disappearance of, gram-positive bacteria, as determined by bacterial cultures from the nose, throat and sputum. In many instances there was a decided decrease in the number of gram-negative bacteria that could be cultured from the same areas following the inhalation of penicillin dust. Not infrequently these results were accomplished following one inhalation treatment. Figure 5 illustrates a blood agar plate of a throat culture prior to the inhalation of 100,000 units of penicillin dust. The profuse growth of streptococcic colonies is entirely absent on plate B, which contains a culture of a specimen taken two hours following the inhalation of 100,000 units of penicillin dust. Another culture, made twenty-four hours after treatment, showed no growth of bacteria. Penicillinase was added to all cultures, so that any penicillin present in the material obtained for culture would be neutralized; thus, favorable changes in the bacterial flora of the upper part of the respiratory tract, as evidenced by the bacteriologic results reported in tables 2, 3 and 4, reflect the beneficial effects with the penicillin dust in situ and are not the

material in the table is arranged according to the extent of the growth of a given organism before and after the course of treatment. It is interesting to note that all of the organisms, including gram-negative bacteria, were appreciably influenced by the treatment. Prior to inhalation of penicillin dust 14 patients had a heavy growth of *Streptococcus viridans*, 10 showed a moderate growth and 1 had a light growth. After a course of treatment, there was 1 instance of heavy growth, 4 of moderate growth, 7 of slight growth and 13 of no growth after seventy-two hours of incubation on blood agar plates. In the cases of *Diplococcus pneumoniae* there was one of heavy growth, 10 with moderate growth before inhalation of dry penicillin. After treatment the *Diplococcus pneumoniae* disappeared in all 11 patients.

Table 3 indicates that organisms in the nose quickly disappeared after inhalation of dry penicillin.

Table 4 illustrates the effects of the treatment on the sputum specimens. Before treatment 6 patients showed a heavy growth of *S. viridans* and 5 a moderate growth. After inhalation of dry penicillin there was a slight

Fig. 5.—Blood agar plates of throat culture. The culture on the left was made prior to inhalation of 100,000 units of penicillin dust. The culture on the right was made two hours following the inhalation of 100,000 units of penicillin dust (penicillinase was added).

growth in 4 cases and no growth in 7 cases. In 1 case there was a moderate growth of *D. pneumoniae* and a slight growth in 2, which disappeared in each instance following treatment. In 2 cases there was a moderate growth of *Streptococcus hemolyticus*, which completely disappeared after inhalation.

PENICILLIN BLOOD LEVEL CURVES

Figure 6 demonstrates blood levels observed when penicillin was inhaled by means of a mouth inhaler. Six subjects were given 100,000 units of penicillin and hourly blood levels were determined. The same 6 subjects were given 100,000 units of penicillin intramuscularly and comparable blood level determinations were made. The results demonstrate that the peak level is reached in one hour and that therapeutic levels are sustained for about a five hour period.

ALLERGIC REACTIONS

In the first 160 patients treated with the mask the incidence of allergic reactions was 6 per cent. With one exception these reactions were local in character and were manifested as contact dermatitis, stomatitis and posterior pharyngeal irritation. One case was

noted of generalized maculo-papular eruption and itching without other systemic manifestation. Creaming the face with wool fat before and washing with bland soap and water following treatment helped to minimize the reaction considerably in the patients in whom contact dermatitis developed. Since this protective regimen was instituted the incidence of contact dermatitis has been reduced to 3 per cent in a subsequent group of 197 patients.

The nature and extent of allergic reactions noted with the inhalation of penicillin dust have been altered since the plastic mouth inhaler has been put into use. There has been, so far, no evidence of contact dermatitis noted with the use of the mouth inhaler. There is little chance of penicillin dust coming in direct contact with the skin of the face. The reactions noted with the mouth inhaler have been primarily those of posterior pharyngeal irritation and stomatitis. Up to the time of writing, 3 per cent of the patients exhibited this type of reaction with this device. There were no instances of angioneurotic edema of the upper respiratory passages or generalized anaphylactoid manifestations with the use of the mask or the mouth inhaler in over 357 cases.

The development of contact dermatitis is no contraindication to continuing treatment, provided that the

three days. The "common cold" syndrome of acute rhinitis, lacrimation, nasopharyngitis and general malaise responded to inhalation therapy. Forty-two per cent were considered cured; 38 per cent were judged as 3 plus improved. In many instances the penicillin dust seemed to exert a vasoconstrictor action

of the mucous membrane of the nose and throat. Patients stated that they could breathe more freely through the nose and the stuffiness and congestion of the acute rhinitis often improved immediately after treatment. Also, on occasion the pain of an acutely sore throat was ameliorated in one-half to one hour following a treatment. These phenomena cannot be fully explained on the basis of the known properties of penicillin and need further investigation.

BRONCHIECTASIS

The aerosol method probably has its greatest merit in diseases affecting the surfaces of the bronchi, such as in bronchitis and bronchiectasis. The most notable results were obtained in bronchiectatic patients who showed toxic absorption from the disease process, as evidenced by loss of weight, low grade fever and profuse amounts of sputum. Pathologic changes were evident on roentgenologic examination. Thirty-eight patients with bronchiectasis were treated. Thirty of the patients received inhalation of 100,000 units of penicillin

dust three times daily for varying periods of time. Eight received combined parenteral and inhalation therapy.

Twelve of the 38 patients (32 per cent) with bronchiectasis showed much improvement, as evaluated by the patients, attending physicians and authors. The disease in these patients had remained in a quiescent form two to eight months following the course of

Fig. 6.—Average blood levels of penicillin obtained in 6 subjects. patient is seriously in need of such treatment and precautions are taken to protect the patient locally and with antihistaminic drugs. Continued use in patients in whom contact dermatitis develops has, as yet, failed to produce any untoward systemic reactions.

GENERAL RESULTS

The clinical results from the inhalation of penicillin dust have been gratifying (table 5). Some conditions responded dramatically, while others progressed slowly, requiring more persistent treatment. In most instances, however, it was believed that this form of treatment was of definite value. The bronchiectatic patients serve, perhaps, best for evaluation of clinical results. In these patients spontaneous remission of the disease is not likely to occur. The results obtained in these patients in our series can be attributed justifiably to this particular type of treatment. In this group improvement of varying degree was obtained in all cases.

The patients with bronchial asthma and chronic bronchitis had moderate to decided improvement, although the allergy persisted to a decreased degree. Patients with asthmatic conditions of bacterial origin improved remarkably.

The patients with acute rhinitis and laryngotracheal bronchitis usually recovered completely within one to

treatment, with one to two inhalations of penicillin dust a week to maintain them free from infections of the respiratory tract.

One patient had a large pulmonary abscess complicating his bronchiectasis. This cleared up gradually following two hundred and ten inhalations of penicillin dust during his hospital stay and ninety similar treatments at home. Seventeen patients (44 per cent) were considered moderately improved. Three were given a series of treatments before and after lobectomy. The rest had only slight amelioration of symptoms.

Before the use of the present method, many patients with chronic pulmonary disease were not given adequate treatment because of the expense of prolonged hospitalization and equipment. The mask or inhaler utilizing dust aerosol permits the start of treatment in the hospital and continuation at home, or it permits a patient to go about his business without loss of time and with minimum expense.

Sufficient data are not available from our studies employing streptomycin dust to permit a clinical evaluation. Five patients have received this treatment for

periods over ten days. The gram-negative bacteria have disappeared from the sputum in all instances, leaving a mild to moderate growth of yeast cells. In only 1 case stomatitis developed after three days of treatment. This cleared up in three days after use of the drug was discontinued.

COMMENT

One could anticipate the destruction of penicillin-sensitive organisms when placing penicillin dust at the bacterial site. There were, however, two unknown and important questions which could not be evaluated beforehand. First, would the inhalation of penicillin dust in 100 per cent concentration give rise to serious untoward reactions? Second, what clinical results would be obtained by such a procedure? Among 357 patients treated by inhalation of penicillin dust the allergic reactions were less than would have been anticipated. The best explanation is that penicillin in dust form (50 to 100 mesh in size) is absorbed over a relatively long period of time. Slow absorption is indicated by the presence of therapeutic blood levels four to five hours after inhalation. The rate and extent of absorption of an antigenic substance modifies the nature of the response to that substance. It is theoretically possible that the desensitization of penicillin-sensitive persons may be taking place by virtue of a slow

absorption phenomenon. In view of the paucity of systemic reactions it appeared justifiable to continue to treat seriously ill patients, such as those with bronchiectasis, in spite of the presence of contact dermatitis. Continuation of such procedure has not as yet produced any systemic reactions. In 1 case the contact dermatitis eventually disappeared and did not recur with subsequent treatment.

The authors are aware of the difficulties attendant on the evaluation of clinical data. However, the clinical results obtained from this dry aerosol therapy were most gratifying. The method is simple and inexpensive. One hundred and thirty-four patients (37.5 per cent of all patients treated) were judged as greatly improved and 129 patients (36 per cent) as moderately improved. Therefore, 73.5 per cent of the entire group had a satisfactory amelioration of symptoms.

It should be emphasized that only in relatively mild bacterial infections of the upper respiratory passages can penicillin dust be relied on as the total treatment, and, if there is not a rapid response in these cases, parenteral antibiotic administration, biologic therapy or treatment with sulfonamide drugs may be necessary. In such diseases as chronic sinusitis, bronchiectasis and bronchial asthma associated with infection, measures directed at securing drainage, combating allergies, liquifying and the like must supplement the treatment.

SUMMARY AND CONCLUSIONS

A simple apparatus for the inhalation of penicillin dust has been developed, making penicillin inhalation therapy easily available for home and office use.

Three hundred and fifty-seven patients were treated with the inhalation of 100,000 units of penicillin dust one to three times daily. Inhalation therapy was continued at home for varying periods of time in all cases of bronchiectasis.

Throat, nose and sputum cultures showed decided diminution of the gram-positive bacteria. In many instances the gram-negative bacteria decreased also.

Penicillin blood level curves indicated absorption from the respiratory tract. Maximum levels of penicillin in the blood are obtained one hour after inhalation. Therapeutic levels are maintained for a period of five hours following the inhalation.

The incidence of allergic reaction in the 357 patients treated by this method was 3 to 6 per cent. The reactions were local in character, manifested as contact dermatitis, stomatitis and posterior pharyngeal irritation. It would seem that the gradual rate and extent of absorption of penicillin dust may account for the low incidence of systemic reactions.

The continued use of penicillin dust in seriously ill patients (with bronchiectasis) in whom contact dermatitis develops failed to produce any systemic reactions.

This method lends itself particularly to the treatment of bronchiectasis. Initial improvement can be obtained usually within ten days to two weeks and can be maintained by continued treatment at home.

Streptomycin dust is now being used, and with the exception of 1 case of stomatitis no untoward reactions have been noted.

While inhalation of penicillin dust almost invariably produced improvement in all types of bacterial infections of the upper part of the respiratory tract, it should again be emphasized that it cannot always be relied on as the total treatment of these infections, to the exclusion of intramuscular or intravenous administration of penicillin, attention to allergic sensitivity, local drainage of sinuses and bronchiectatic cavities and the like.

GENERAL PRACTITIONERS SESSION

THE UNKNOWN DIABETIC AND HOW
TO RECOGNIZE HIMRUSSELL M. WILDER, M.D.
Rochester, Minn.

The diagnosis of diabetes mellitus, in a frank instance of the disease, is one of the easiest that can be made reliably. Even in patients who are symptomless, diagnosis is possible on the basis of a dependable determination of the level of sugar in blood taken from the patient after twelve or fourteen hours of abstinence from food. With the Folin and Wu technic for blood sugar analysis, the finding of something more than 120 mg. per hundred cubic centimeters of reducing substance expressed as dextrose establishes the fact of diabetes with an error which is smaller, I suspect, than that involved in the diagnosis of any other disease. A degree of overstatement is involved in this assertion and certain reservations will be mentioned later.

On the other hand, to be able to affirm with confidence that glycosuria in a given person is significant of diabetes when the fasting blood sugar is lower than 120 mg. per hundred cubic centimeters requires much discrimination. In cases such as this difficulties are encountered and a considerable incidence of error is involved. Mistakes are made in both directions. On the one hand, mild but potentially disabling diabetes is not infrequently neglected, and on the other hand persons are labeled diabetic on insufficient evidence. I could cite numerous examples of patients who, on one examination, showed a trace of sugar in the urine which was ignored at the time by their physicians and who later returned with frank diabetes mellitus. In many of them the fasting blood sugar was determined and a normal value was obtained. I also could cite instances in which significant injustice has resulted because a diagnosis of diabetes mellitus was based on an improperly interpreted dextrose tolerance test, with the result that the person either was denied life insurance or had to pay an increased premium for insurance. Which of the two mistakes is considered the more serious depends on points of view. Both are regrettable, but if I had to choose between them I should say that the advantage to persons with potential diabetes of being put on their guard and thereby protected against development of frank disease outweighs the occasional injury to persons for whom a diagnosis of diabetes is unjustified. In other words, I prefer to err, if err I must, on the side of certainty that there is no diabetes. A good rule, in my opinion, is to regard all positive reactions for reducing substances in the urine as indicative of diabetes mellitus until proved otherwise, but to obtain in all such cases an examination of the blood and, if this is normal, an oral dextrose tolerance test. If the result of the tolerance test is surely negative all is well and good; if it is distinctly positive, even when the fasting blood sugar level is normal, the disease is diabetes mellitus; if the test is equivocal, which unfortunately is not infrequent, a diagnosis is unjustified but reexamination later or repeatedly ought to be carried out.

MELITURIA ALONE NOT DIAGNOSTIC

All too often diabetes has been diagnosed on the sole basis of a finding of some reducing substance in the urine. This is inexcusable, since a number of benign conditions are thereby mistakenly labeled diabetes mellitus. Such patients are subjected to the injury of whatever stigma attaches to the diagnosis of diabetes; they also not infrequently are subjected to unnecessary restrictions of their diets or, worse still, to injections of unneeded insulin. The possibility of error in diagnosing diabetes from urinary tests alone is very great. The incidence of nondiabetic melituria is high. In a series of insurance examinations reviewed by Exton¹ diabetes was responsible for positive results of urinary tests in only about half of 800 specimens of urine in which the amount of reducing substance expressed as dextrose was 1 per cent or less. The positive results in the balance of the specimens were caused by something other than dextrose or, if due to dextrose, diabetes could be ruled out by a tolerance test. If the reducing power of the urine is more intense, with the reducing substance, expressed as dextrose, exceeding 1 per cent, the likelihood of error is diminished. In 97 per cent of 200 such specimens of urine the reducing substance was dextrose. However, in some of them blood sugar levels remained within normal range on an oral tolerance test so that diabetes mellitus could be excluded.

Reducing substances other than dextrose which appear in the urine include lactose, galactose, fructose, maltose, mannoheptulose and pentose. It also has been suspected that ascorbic acid (vitamin C) may, at times, provoke positive urinary tests. This, however, seems unlikely, since the reducing power of ascorbic acid is something less than that of dextrose, and even very large therapeutic doses (1,000 mg.) seem not to be sufficient to affect the reducing power of the urine. Specific chemical tests are available for the identification of the sugars other than dextrose found in urine, but such identification represents a refinement of little practical importance. None of these other meliturias affect the patient's health, and the amount of any of these substances in the blood probably never is sufficient to influence significantly the reducing power of the blood, whereas the diagnosis of diabetes depends primarily on the level of sugar in the blood.

BLOOD SUGAR VALUES

I stated earlier that a fasting venous blood sugar value of 120 mg. or more per hundred cubic centimeters is acceptable, with certain reservations, as diagnostic of diabetes mellitus. Infections, recent injuries or hyperthyroidism may elevate the concentration of blood sugar and confuse the issue; so also may hyperpituitarism, functioning adrenal tumors, encephalopathies and acute coronary occlusion. Occasionally the blood sugar level rises in renal failure and likewise with arteriosclerotic changes of the kidneys. Due allowance must be made for such conditions. Fasting blood sugar values tend to rise with age. However, they seldom normally exceed 120 mg. per hundred cubic centimeters. On the other hand, low fast-

From the Division of Medicine, Mayo Clinic.
Read in a panel discussion on Treatment of the Ambulatory and Hospitalized Diabetic Patient at the interim meeting of the American Medical Association, Cleveland, Jan. 8, 1948.

1. Exton, W. G.: Differential Diagnosis of Conditions Associated with Sugar Excretion, New York State J. Med. 36: 1545-1553 (Oct. 15) 1936.

ing values for blood sugar occur in true diabetes mellitus, and care must be taken not to be misled by them. In many cases, especially in children, a stormy onset of diabetes is followed by remission which may last for several months, and in this period fasting blood sugar values may fall within the normal range. Likewise in many cases of mild diabetes restriction of the diet is sufficient to bring fasting values down to normal levels. Malingers effect the same either by fasting or by taking a dose of insulin shortly before the time of examination. In such instances, examination of the urine and blood for sugar forty-five to sixty minutes after a meal liberal in carbohydrate may be helpful, especially if the value then is found to be not less than 180 mg. per hundred cubic centimeters. Otherwise a tolerance test is indicated.

THE DEXTROSE TOLERANCE TEST

The dextrose tolerance test should not be made if the diagnosis of diabetes has previously been established either from the history or from the finding of an abnormal elevation of the fasting blood sugar. It gives imperfect information about the severity of diabetes, and the ingestion of the necessary amount of dextrose is not without injurious potentiality when the diabetes is of much severity.

There is no unanimity of opinion as to how the tolerance test should be conducted. Consensus favors the one dose, three hour test with a solution of dextrose administered by mouth and determinations of blood and urinary sugar made before and at spaced intervals after the patient begins to drink the solution. Whether 50 or 150 Gm. of dextrose is given makes little difference. The dose commonly employed is not less than 50 nor more than 100 Gm. for adults and 1 Gm. for each pound (0.5 Kg.) of body weight for children. Authorities agree that the patient should have fasted during the twelve or fourteen hours before the test is made, and that his diet must not have been restricted for at least three days beforehand. The majority of those experienced with the test place little emphasis on the peak of the blood sugar elevation that follows the ingestion of the dextrose in thirty to sixty minutes. They regard as more important diagnostically the rate of return of the blood sugar level to the normal range of fasting values (70 to 120 mg. per hundred cubic centimeters). The peak when the tolerance is normal rarely exceeds 180 mg. and rarely is accompanied by glycosuria. The return of the blood sugar level to the normal range of fasting values occurs between the second and the third hour. The peak in diabetes is attained later than the hour period and the return is retarded. Glycosuria accompanies the elevated blood sugar values.

Abnormal Responses; Not Diabetes.—Even a high peak which is accompanied by excretion of sugar in the urine is not considered diagnostic of diabetes mellitus when the blood sugar level returns to the range of normal fasting values within two hours. A response of this type is occasionally observed in hyperthyroidism; it also may be seen in patients who have undergone gastrectomy. It has been called the lag or storage type of response, but probably is explained on the basis of an increased rate of absorption of the dextrose.

A response of the sugar level of the blood which is normal in its pattern but is accompanied by glycosuria

is interpreted as renal glycosuria. This is a benign condition dependent on a lowered glucose threshold in the kidneys. The amount of sugar in the urine will vary with the diet. It also varies from case to case with the degree of depression of the threshold. A threshold lower than the level of blood sugar during fasting permits continuous glycosuria. One higher than the fasting level but lower than the normal threshold is accompanied by discontinuous or cyclic glycosuria, the sugar appearing only after food is taken.

The renal threshold is depressed in pregnancy. This indeed is the explanation of most instances of the so-called melituria of pregnancy. The sugar excreted is dextrose, not lactose, as is frequently supposed. Lactosuria occurs uncommonly until lactation has begun.

The renal threshold usually is normal in diabetes mellitus but occasionally may be depressed. Sugar then will be excreted even when the treatment of the diabetes with diet or insulin or both is adequate in all respects. The diabetes in patients with this abnormality is difficult to treat, for the reason that tests of the urine of these patients serve imperfectly as guides to the desirable dosages of insulin.

Pseudodiabetic Responses.—The same conditions which may elevate the fasting level of the blood sugar of normal persons modify the response of the blood sugar level in the glucose tolerance test. They include acute or chronic sepsis, physical injury, other endocrine diseases, especially hyperthyroidism, hyperpituitarism or active adrenocortical tumors, coronary occlusions, diseases of the liver, some encephalopathies, advanced chronic nephritis and muscular dystrophies. Furthermore, if a diabetic type of response is to be interpreted correctly the patient must not recently have engaged in unusual physical exertion or have taken alcohol or any drug, nor must he have been subjected to starvation, to a diet restricted in carbohydrate or to any recent emotional excitement. Tobacco smoking or chewing immediately before or during the test period will elevate blood sugar values, and apprehension over the venipunctures required by the test may provoke a diabetic type of response in some adults, but especially in young children.

In other words, tests for dextrose tolerance, if they are to give reliable results, must be made only under strictly basal (standard) conditions, and when any disease is present other than the suspected diabetes a positive response must be interpreted with caution. In the presence of another disease a diagnosis based exclusively on the results of a dextrose tolerance test can be no more positive than "diabetes suspected," but in that case other examinations should be made later and the patient should remain under the supervision of his physician until the suspicion is removed. True diabetes persists, so that in time a decision almost always can be reached, either on the basis of subsequent tests or as a result of the development of conspicuous symptoms. A diabetic-like response to the tolerance test is conclusive evidence of the presence of diabetes only in the absence of any other cause for disturbed carbohydrate metabolism.

DIABETIC SURVEYS

It is not to be doubted that many incipient cases of diabetes long remain unrecognized. Therefore knowledge as to the incidence of this disease can only

be obtained by satisfactory surveys and examination of all persons not previously diagnosed as diabetic. For such examinations some type of screening is required which involves a minimum of time and inconvenience for the persons examined. It might be wise to meet this problem by adopting a suggestion based on the opinion of many experts; namely, that if only one blood sample is available no other single determination of blood sugar is as useful as the one obtained two hours after the oral administration of a standard dose of dextrose. The briefest possible history also would be necessary because interpretation of a borderline two hour blood sugar value should properly be more severe when the person has a history of diabetes in his family.

The suggestion then would be to instruct examinees to eat freely of carbohydrate for three days and present themselves before the morning meal for testing, to give 50 Gm. of dextrose previously dissolved in 250 cc. of water flavored with citric acid and chilled and to secure after two hours a sample of arterial—that is, capillary—blood from finger or ear.

While there is advantage in use of venous blood in the type of dextrose tolerance test described before, British clinicians long have made their tolerance tests by using arterial blood. This is preferable in survey work, especially since micromethods are available so that a single drop of blood suffices for a satisfactory determination of sugar. The peak of the blood sugar response is higher when arterial blood is used than it is when venous blood is employed, but for the purposes of a survey we are not concerned with peak values and at two hours the differences between the sugar level in arterial and venous blood has disappeared. Therefore a value of 120 mg. or less could be taken as excluding diabetes, and one above that value would mean that the patient is a diabetic suspect. The procedure would, I think, pick out nearly all the persons having diabetes, although with them would be included a small group who did not have it. However, the positive but doubtful reactors could be subjected to more careful study afterward. For them I would resort to subsequent repeated observations until a diagnosis could be definitely established.

Less reliable for screening purposes would be a blood sugar determination obtained an hour after the morning meal, with this meal made rich in sweets and other carbohydrates. A blood sugar value of 170 mg. per hundred cubic centimeters would then represent the dividing point between persons who do not have diabetes and diabetic suspects.

Least reliable would be dependence on examination of the urine, although initial screening might be accomplished by testing urine collected after a breakfast which was rich in sweets and other carbohydrates. This would miss some diabetic persons, that is, those who had been on restricted diets earlier, but a brief history might suffice to pick up most of them. It would, of course, include many persons who were not truly diabetic, especially those with renal glycosuria. However, if the criterion adopted was a urine with not less than 1 per cent of reducing substance expressed as dextrose, most instances of melituria from sugars other than dextrose would be excluded.

The importance of early detection of diabetes cannot be overemphasized. Treatment now is usually postponed beyond the time when much restoration of

pancreatic island function can be expected. Intensive management of diabetes offers greatest promise when it can be instituted at the very onset of the disease. However, this involves detecting the disease in its incipience, which rarely has been possible. For this reason all health examinations should include some screening tests for diabetes with a careful follow-up of the diabetic suspects which they disclose. An examination such as this made every year in all schools, college and other institutions, also in all business firms and factories, would contribute greatly to the public health. For this reason also the present active interest of the United States Public Health Service in undertaking diabetic surveys of communities, as in Oxford, Mass., and in Florida, should receive all possible support from practitioners of medicine and specialists in diabetes.

SUMMARY

The diagnosis of diabetes has been discussed with special reference to the significance of positive reactions for sugar in the urine, elevated blood sugar values and the oral dextrose tolerance test. The tolerance test can lead to error unless pseudodiabetic responses are recognized for what they are and the test is made under strictly basal (standard) conditions. Procedure for discovering, by survey, previously unrecognized diabetes also has been considered.

MEDICAL AND SURGICAL VASCULAR COMPLICATIONS OF DIABETES

LESTER J. PALMER, M.D.
Seattle

The term complication as employed in reference to a chronic disease is commonly used to refer to an associated disease as well as to a condition more directly the result, per se, of the primary condition.

In diabetes, a vascular complication, or associated vascular disease, is considered, as to degree at least, to be the direct result of the disturbed metabolic state, or greatly aggravated by it in both tempo and time.

Many pathologic conditions observed in the diabetic person are most favorably influenced through our ability to control the diabetes. Thus, for example, the person with controlled diabetes is less susceptible to infection and acidosis than the one with uncontrolled diabetes. Surgical procedures, acute and elective, trauma, neoplastic disease and even pregnancy—this latter if especially approached—do not present to the surgeon and internist a more formidable problem in the diabetic person than in the nondiabetic.

Premature vascular disease, with its interference with adequate circulation, does not seem to be so directly influenced in a favorable direction by good diabetic control alone. Since not all persons with diabetes over a period of years of diabetes contract premature and serious vascular damage, and since some persons with well controlled diabetes do contract early and serious vascular disease, perhaps one is justified in the following reasoning. Either some persons with diabetes are predestined to early vascular disease through heredity, and diabetes only aggravates this predisposition, or

Read in a panel on Treatment of the Ambulatory and Hospitalized Diabetic Patient at the interim meeting of the American Medical Association, Cleveland, Jan. 8, 1948.

there is associated in a varying degree with diabetes, and more frequently with poorly controlled diabetes, a disturbance of fat metabolism which is in itself responsible for the vascular damage. At present our knowledge of the disturbed metabolism of diabetes is so limited, although it is currently rapidly increasing, that much of such reasoning is necessarily without basis of fact.

The major part of our attention to vascular disease in the diabetic person must be given to prevention. Limited by our present knowledge, we are confined as follows in this respect.

Many statistics show that vascular disease has a distinctly lower incidence in the presence of well controlled diabetes. Statistics to the contrary usually err because they are based on deficient records or too short periods of observation. Many of us have in our files case records of diabetes of twenty to twenty-five years' duration and over, in which it is impossible even by the most detailed study to demonstrate any evidence of vascular disease. There is, however, considerable evidence to indicate that fat should not be employed in the diet beyond that amount needed to supply adequate calories while prescribing liberal but subnormal amounts of carbohydrates. Also there is considerable evidence to support the theory that fats low in cholesterol are safest. As to protein, there is considerable evidence to justify the opinion that protein may be allowed without disadvantage, and frequently with distinct advantage, more liberally than has been done by many authorities in the past.

Improved effort to prevent or delay vascular damage in the future must follow amplification of our present knowledge of the disturbed metabolism.

Once vascular disease has developed to a degree that interferes with normal function, the problem in the person with diabetes, except for the necessity for control of the diabetes, is rather similar to that in the non-diabetic person.

In the diabetic patient vascular disease is most apt to be cardiovascular renal disease. Myocardial infarction, secondary to disease of the coronary arteries, is the major cause of death among persons with diabetes. Cerebrovascular accidents and vascular renal disease vie for second place. In the juvenile group renal disease is pressing for first place in the list of causes of death. Here we see most often the characteristic lesion of intercapillary glomerular sclerosis.

Gangrene of the lower extremities is a most frequent complication not uncommonly resulting in crippling amputation. Although it may occur in the absence of severe vascular damage, it is the degree of vascular damage that most frequently determines the susceptibility to, and the course of, infection and trauma in this area. Therefore great emphasis must continuously be placed on care of the feet, thus preventing as far as possible this serious complication. The greater the degree of vascular damage, the greater is the need for painstaking preventive effort and for adequate attention to minor lesions.

Hypertension is so commonly found associated with diabetes that the finding is almost expected past middle life. Among young persons with diabetes of over twenty years' duration, a national authority recently found hypertension present in 40 per cent. The hypertension associated with diabetes, in many instances at least, may or may not be the type of hypertension com-

monly classified as essential. The distinctly high incidence, however, is not denied.

Retinitis is probably the most discouraging vascular complication. Perhaps this is so discouraging because the incidence is so high among young persons. Dr. Priscilla White has recently found that 85 per cent of young persons with diabetes of over twenty years' duration showed evidence of retinitis. Other studies have indicated that the incidence is even more nearly universal than this figure. Although the incidence is distinctly lower among persons with continuously well controlled diabetes, there is an undeniable relationship between retinitis and duration of the diabetes. Early retinal damage may be slowed or even checked in its progress by the institution or reinstitution of exacting diabetic control. At present however, all other measures have proved to be of no assistance. However, reports of recent observations of the effects of rutin and hesperidine are promising in a somewhat limited percentage of the groups studied.

Vascular complications in the diabetic person are most often medical. The surgeon is relatively infrequently called on to assist, except when the lesion exists in a lower extremity or the eye. Antibiotics and the newer bactericidal drugs, especially the sulfonamide group, have proved a boon to the diabetic person. They have made it possible to bring infections under control quickly. They have lowered the mortality of elective surgical procedures. In the presence of vascular disease they have made it possible to carry out more conservative surgical procedures on the extremities than would have been attempted previously. For example, transmetatarsal amputation has not infrequently been successful in recent years with their assistance, whereas formerly only higher amputation would have been attempted.

Except for proper control of the diabetes, medical measures are largely directed at symptomatic relief, or at best are only retarding in their influence. Vascular antispasmodics of all types may be distinctly so classified. Spasm is not the controlling factor in vascular disease as it is seen in the diabetic person. For this same reason drugs or surgical procedures which produce sympathetic block at various levels produce only temporary relief.

Vascular disease among that group of diabetic persons with onset in childhood is especially disturbing because twenty to twenty-five years ago, shortly after the advent of insulin, our highest hopes for prevention of vascular disease rested in this group. The Joslin group has recently pointed out, however, that our current statistics in this regard are probably the worst that we will ever see, since these records being studied are those of diabetic persons who for not more than half of their diabetic life have had the advantage of good diabetic control.

At present there is a definite relationship between the incidence and degree of vascular disease in the person with diabetes, and the duration of the disease. At least until we know more of the facts regarding the total metabolic disturbance in diabetes, we must place our greatest confidence in our ability to maintain normoglycemia and aglycosuria in the presence of an adequate nutritional intake. We must diligently apply in a practical manner what knowledge we have today, for even tomorrow further light of great degree may be thrown on our problem. Let us not, either as physicians through failure to apply present accepted

therapeutic principles, or as patients through failure to give full cooperation, fail to maintain a physical status which will permit the patient to take advantage of the newer knowledge of tomorrow. As biochemists and physiologists slowly but progressively unfold further and further the manifold mysteries of metabolism, we will come to understand more thoroughly the problem of diabetes and be able to base on this knowledge a more effective therapy.

INSULIN AND DIET

HENRY T. RICKETTS, M.D.
Chicago

My colleagues and I, in common with all others dealing with diabetes, have long been disturbed by the increasing incidence of severe degenerative lesions in our patients. It appeared to us that data obtainable thus far from human beings were unsatisfactory as an aid in solving this problem, because of the impossibility of keeping such patients under sufficiently controlled conditions for sufficiently long periods of time. It seemed a reasonable expectation that if we could collect a series of diabetic animals and maintain them with known amounts of glycosuria for years, perhaps for the duration of their lives, observing the changes in the blood and tissues from time to time, we might gain more information about the mechanism by which the degenerative lesions occur than has been possible in studies of clinical material.

We have proposed, and indeed have begun, to render a good many dogs diabetic with alloxan, perhaps 100 if we can, and to divide them into two groups, one of which will be kept as nearly free of glycosuria as possible with insulin, the other being allowed to run far out of control. Half of each group will be on a high carbohydrate-low fat diet and half on a low carbohydrate-high fat diet in an effort to determine whether hyperglycemia and hypercholesteremia favor the development of degenerative complications.

Fundamental in any consideration of diet and insulin in the treatment of diabetes is the question of what we as physicians are trying to accomplish. Do we want to control glycosuria as completely as possible, consistent with the avoidance of hypoglycemia? Or are we to be content with allowing patients to eat much as they please, excreting large amounts of sugar in the urine, as long as they do not have thirst and polyuria, and taking only enough insulin to avoid ketosis?

It is self evident, I trust, that if the latter point of view is adopted, any discussion of diet is meaningless. There is no diet, in the usual sense, and the problem of insulin becomes negligible.

My personal views on the subject may be summarized as follows: If no one has proved that persistent hyperglycemia is harmful (and I may say that there is excellent evidence of harm in animals), neither has any one, including the advocates of the free diet, proved that it is not. Until such proof is at hand, it will be unwise and unsafe to abandon attempts to keep the blood sugar reasonably close to normal. I will be the first to admit that in the young unstable diabetic person that goal is often difficult, if not impossible, of

attainment without running the risk of a more immediate and serious danger, that of severe hypoglycemic reactions. In such situations one is forced to compromise with principles. The dose of insulin must be adjusted so that hypoglycemia never occurs, and this, in the unstable cases, means inevitably, though none the less regrettably, considerable glycosuria some of the time.

Important aspects of a diabetic diet are:

1. Establishment and maintenance of normal nutrition
 - (a) If patient is too fat, reduce him
 - (b) If patient is too lean, fatten him, slowly
2. Calories (these are considered before carbohydrate, protein and fat): Basal, 20 to 25 calories per kilogram (10 per pound) of standard weight
 - Add 30 per cent for sedentary workers
 - Add 50 per cent for more active persons
 - Add 100 per cent or more for laborers
3. Protein (1 Gm. per kilogram [$\frac{1}{2}$ Gm. per pound] of body weight)
4. Carbohydrate and fat (one-half the remaining calories [total calories minus protein calories] in each)
 - Low carbohydrate diet only for new patients not already receiving insulin
5. Minerals and vitamins

A diet for an office worker (moderate activity) whose both actual and ideal weights are 70 Kg. might be calculated as follows:

Body weight	70 Kg.
Basal caloric requirement (70×20 calories)....	1,400 cal.
Add 50 per cent for moderate activity.....	700 cal.
Total caloric requirement.....	2,100 cal.
Protein allowance (1 Gm. per kilogram).....	70 Gm.
Protein calories (70×4 calories).....	280 cal.
Balance to be supplied by carbohydrate and fat..	1,820 cal.
Carbohydrate calories ($1,820 \div 2$).....	910
Carbohydrate grams ($910 \div 4$).....	228
Fat calories ($1,820 \div 2$).....	910
Fat ($910 \div 9$)	110 Gm.
Final diet prescription	
Carbohydrate	228 Gm.
Proteins	70 Gm.
Fat	110 Gm.

Carbohydrate may be distributed, percentage wise, between the three principal meals and a bedtime feeding in some such proportion as 20-35-35-10.

It is necessary to emphasize to the patient the importance of the quantities as well as the kinds of food, the constancy of carbohydrate intake from day to day and the ability to make simple substitutions to avoid monotony and yet keep constancy.

Four types of insulin are now available: soluble or "regular,"¹ protamine zinc, globin and mixtures of these prepared by the physician or the patient.

The figure shows the various blood sugar time curves obtained with these different forms of insulin. All of the curves were obtained for the same diabetic patient on different days, with a constant regimen which consisted of the patient's receiving feedings of milk every two hours throughout the twenty-four hour period. This was to insure that his state of hydration and nutrition would be constant and unvarying throughout the observations. On one of the days he was given a dose of 35 units of protamine zinc insulin, and his blood sugar went up a little for almost four hours, then gradually went down, until at the end of twenty-four hours it had reached its lowest point. In contrast to protamine zinc insulin, regular or crystalline insulin, given in exactly the same dose, reached its peak of activity at six hours and gradually tapered off, so that at the end of fourteen or sixteen hours the level of blood sugar had returned to its initial

Read at the interim meeting of the American Medical Association, Cleveland, Jan. 8, 1948.

This study is being supported by a grant to the University of Chicago by the Division of Research Grants and Fellowships, National Institute of Health, United States Public Health Service.

1. The manufacture of crystalline insulin (solution of zinc insulin crystals) is being discontinued.

point. If regular insulin and protamine zinc insulin are combined, are mixed in the syringe in the proportion of 2 parts of regular to 1 of protamine zinc insulin, one secures a curve which is, on the whole, intermediate between that of protamine zinc insulin and that of crystalline or regular insulin alone. It is interesting that this type of curve closely parallels the curve produced by globin insulin in a similar total dose.¹

These four types of curves, then, can be taken to characterize the action pattern of the different types of insulin now in common use.

With reference to protamine zinc insulin, it should be emphasized that the curve shown in the figure is that which is obtained only after a single test dose of the substance.

Protamine zinc insulin, when given daily, at twenty-four hour intervals, has an entirely different type of activity.

Soon after the discovery of protamine zinc insulin, it began to appear from clinical results that its activity was relatively constant throughout the twenty-four

ent that the action of protamine zinc insulin is the same, whether it is given in the morning or in the evening.

Now, in order to establish that if a short-lasting insulin were given in the morning as against the evening the curves would be different, other curves were obtained. Regular insulin was now given for some time in the evening, with one type of curve resulting. Regular insulin was then given in the morning, with the other type of curve resulting. Finally, the patient was given no insulin, and a curve was obtained which was similar in shape to the curves produced by protamine zinc insulin. This constitutes further evidence that the activity of the protamine zinc insulin is a relatively constant matter. It simply lowers the general level of the blood sugar.

If protamine zinc insulin does, in truth, act fairly constantly throughout twenty-four hours, it helps one to understand why it is not able to take care of the food intake in persons with severe diabetes, in whom the pancreas is unable to produce a little insulin in response to the ingestion of food. It explains, on the other hand, why protamine zinc insulin is effective in persons with mild diabetes, who have a good pancreatic reserve.

These differences in the effectiveness of protamine zinc insulin from one type of patient to another are illustrated by curves obtained for persons with diabetes of varying degrees of severity before and after partaking of food. It is apparent that in each case protamine zinc insulin controls the fasting blood sugar very well. The postprandial blood sugar, however, is well controlled only in the milder cases, and the severer the diabetes the less successful is this preparation in returning the blood sugar to normal two or three hours after a meal. Such failure is most pronounced in the most severely diabetic subject we know of, the totally depancreatized dog.

In patients with severe diabetes, therefore, protamine zinc insulin must be supplemented by a quickly acting insulin if the blood sugar after meals is to be kept within reasonable limits. This type of insulin (regular or crystalline) is given at the same time as the protamine zinc insulin, before breakfast, and may be administered either separately or as a mixture. It must not be forgotten, however, that the effect of a dose of regular insulin given separately is different from its effect when mixed with protamine zinc insulin. In the latter case a considerable proportion of the regular insulin is converted to the protamine complex by the excess of protamine present.

Dr. Colwell of Chicago, Dr. Peck of Indianapolis, Dr. McBride of St. Louis and Dr. Wilder at the Mayo Clinic have been actively concerned in the use of insulin mixtures in the syringe. One of the advantages is that, in place of having to give two injections of insulin to the severely diabetic patient, whose disease protamine zinc insulin alone will not control, one can add a quickly acting component to the mixture and accomplish about as much in one injection as could be accomplished in two separate injections of crystalline and protamine zinc insulin.

It has been observed by the majority of investigators that a mixture consisting of 2 parts of crystalline or regular insulin to 1 part of protamine zinc insulin fulfils the requirements well for the vast majority of diabetic patients, perhaps 80 or 85 per cent. One must not, however, forget the remaining 15 per

Blood sugar time curves for a diabetic patient obtained with different forms of insulin (Ricketts, H. T.: Certain Aspects of the Newer Insulins, Illinois M. J. 87: 133 [March] 1945). The vertical column of figures at the left shows the number of milligrams of sugar in the blood per hundred cubic centimeters.

hour period. To put this probability to the test, we devised the plan of giving protamine zinc insulin to a diabetic patient first in the morning for several days, testing his blood sugar four times each day, averaging the results and plotting them as a curve. We then gave it to him in the evening for several days, getting a similar series of figures and finally checking again with another morning series represented by still another curve.

It was reasoned that, if protamine zinc insulin had a fairly constant activity throughout the twenty-four hours, then the shape of the blood sugar curve should not be altered, no matter whether the patient received his insulin in the morning or in the evening; the curve ought to be reproducible. If the activity of protamine were not constant, if there were, in fact, a period of maximum activity and then waning activity, as there is with a short-lasting insulin, then it should make a good deal of difference whether one gave the protamine zinc insulin in the morning or in the evening.

It will be apparent, I think (from the curve) that there is little difference except at one point between the results of morning and of evening administration of protamine zinc insulin.

A similar type of observation was made on another patient. Again, the averages were plotted of several days' determination, not of a single day; it was appar-

20 per cent, in whom a different proportion of regular to protamine zinc insulin may be necessary. The advantage of using mixtures is precisely that one can change the proportion of one to the other, as the requirements vary from patient to patient or in the same patient from one time to another.

The diagrammatic representation of Colwell's data indicates the action of regular insulin, protamine zinc insulin and 2 to 1 crystalline to protamine zinc insulin mixture, the action of which lasts less long than that of protamine zinc insulin and begins less abruptly than that of regular insulin. The action is also shown for a 3 to 1 mixture of crystalline to protamine zinc insulin. It must be apparent that, as one increases the proportion of crystalline insulin in a mixture of crystalline and protamine zinc insulin, the onset of action of the insulin is accelerated, with less duration of action.

The principal point, to be made is that by altering the proportion of one type of insulin to the other, one can obtain a type of compound to suit the individual needs in the vast majority of instances.

If air is not injected into the bottle at the time the insulin is withdrawn a vacuum is produced which makes manipulation difficult. Therefore, one ought to inject into the bottle the same number of units of air, so to speak, as of insulin withdrawn from the bottle.

A comparison of globin insulin with other forms of insulin is illustrated in a young girl with relatively severe diabetes. Crystalline insulin given morning and night (12 units each time) led to an extremely high level of blood sugar on arising, which is characteristic of severe diabetes in young persons. The crystalline insulin kept on working all day, and the low point showed that there was a tremendous change in the level of the blood sugar.

Globin insulin given in the same total dosage produced considerably better results and in this case, obviously, had an action which lasted more than twenty-four hours, or at least twenty-four hours, because the fasting blood sugar was much better than with two doses of crystalline insulin per day (breakfast and supper).

A comparison was made of the effect of globin insulin with crystalline insulin alone in a patient with milder diabetes. From the curve for globin insulin and the curve for crystalline insulin, it was apparent that the crystalline insulin, a short-lasting insulin, does a better job in this particular patient than did the globin type. It is not always the case.

In another patient globin insulin obviously failed to have a twenty-four hour effect. Any variation from marketed protamine zinc insulin should have, in my opinion, the minimum requirements of full twenty-four hour activity in all patients, not in some but in all. Unless that criterion is fulfilled, there is little excuse for adopting a long-lasting insulin other than protamine zinc insulin.

Efforts are under way to secure a stable preparation with a shorter duration of activity than that of protamine zinc insulin and a quicker onset of action, and the preparations which we have tried so far have all had twenty-four hour activity in all patients. That, I think, is important. Globin insulin does not have twenty-four hour activity in many patients, and that is one reason that I do not advocate its routine use.

The practical application of the technic of adjusting the patients to diet and insulin can be represented by charts. In the patient with mild diabetes, our custom,

if we have not observed him before, is to give him a diet containing 100 Gm. of carbohydrate distributed equally among the three meals. If, with such a regimen, the patient returns in a week with a record of urinary tests showing that the condition was not controlled with diet alone, a small dose of protamine zinc insulin is prescribed, and since insulin must be taken anyway, the carbohydrate intake is increased to a more nearly normal figure. With mild diabetes, such a maneuver is almost uniformly successful.

If the diabetes is severe, there is a different problem. Treatment of the previously untreated diabetic person is started with 100 Gm. of carbohydrate per day. If at the end of a week it is obvious that insulin is needed, the diet is changed to include 150 or 200 Gm. of carbohydrate. He is given 10 to 20 units of protamine zinc insulin. Protamine zinc insulin in adequate amounts will usually be observed to control the fasting urine specimen.

When one gives the same total dosage in a mixture of 2 to 1, one is likely to effect considerable improvement in results of urinary tests, which can be still further improved, perhaps, by juggling the amounts of carbohydrate among the various meals.

I would like to end on the note with which I began, that my colleagues and I are not yet ready to abandon the goal of careful control of the blood sugar in the treatment of diabetic patients.

ABSTRACT OF DISCUSSION

ON PAPERS BY DRS. WILDER, PALMER AND RICKETTS

QUESTION: Why is it they have so many more men with diabetes at the Mayo Clinic than they do women?

DR. WILDER: There is about an equal number of men and women in the Mayo Clinic. Most statistics on diabetic deaths indicate the presence of more women than men. Most diabetic surveys or at least most complications of diabetic incidence have indicated more women than men. Why our figures were different from those of almost every one else has been a puzzle to us for many years. This has been going on year after year for the last twenty years, at least, with, I will say, 51 or 52 per cent of men and 48 or 49 per cent of women, rather than the reverse in other places. We have felt that perhaps we were getting more accurate figures on sex incidence than Dr. Joslin was, because persons that we see do not come to us because they have diabetes. We have no Dr. Joslin in the Mayo Clinic. They come for everything else under the sun. They are all examined carefully, no matter what the matter is with them. Sugar, when it is found, is followed up by examinations of blood. That has given us our figures. I am interested that Dr. Wilkerson's figures at Oxford, Mass., where, again, everybody was examined, not only those who happened to come because they had diabetes, show a close incidence of men and women. It is true that women outnumber the men a little, but the degree is so small that I wonder whether it really has statistical significance. Likewise in Stockholm, where they recently had a survey of the incidence of diabetes, based on applications for special rations during the war—there was an incentive for these men to present themselves for examination—the incidence of men in most of the decades exceeded that of the women, just as it does with us.

QUESTION: How does the intravenous glucose tolerance test compare with the oral?

DR. WILDER: In the intravenous test one gets a sharper rise, of course. I imagine it is equally useful, provided that one had a mass of experience with it so as to be able to compare the finding in an individual case with the general finding.

QUESTION: Do you use oral glucose generally?

DR. WILDER: We use the oral test exclusively.

QUESTION: Do you consider the "clinitest" reliable for patients to depend on for urine test?

DR. WILDER: We are using the "clinitest" right along in most patients. We teach them the Benedict qualitative test and the "clinitest." They must be urged to keep these tablets from deteriorating, by keeping the bottle tightly closed. When they deteriorate, the patients may be led astray and think that they have different amounts of sugar than they have. However, mistakes also are made with the Benedict test. I had 1 patient who died as a result of diabetic acidosis, led astray by buying Benedict's quantitative solution rather than Benedict's qualitative solution and failing to get a reaction that he recognized as positive.

QUESTION: Please explain how a drop of arterial blood is used in determining diabetes.

DR. E. P. JOSLIN, Boston: Mrs. Leech in our exhibit is determining blood sugars by taking a drop of blood from the ear. There was one thing which I could tell Mrs. Leech today that encouraged her. One of the men formerly working with us, and now in a fairly large city, the other day saw a patient evidently going into acidosis, as he thought. No opportunities for determining blood sugar were available, even in this large city. The physician happened to remember Mrs. Leech's test, carried it out himself, and determined the patient's blood sugar, 600 mg., and the patient came out of coma.

QUESTION: What method of determination of blood sugar do you suggest as being simple but accurate for the doctor who must do his own office blood sugar determinations?

DR. WILDER: I think that this technic which Mrs. Leech is developing is going to be the answer to that question.

DR. HUGH L. C. WILKERSON, Boston: We are conducting a program in diabetes control in two parts of the country, one in Brookline, Mass., where we are doing case finding and general educational work with the public, and also some educational work with diabetic patients. In Jacksonville, Fla., we have a program in diabetes, not just a survey, where we are doing case finding and education of the patient. In particular, we are holding classes for diabetic patients referred to the health department by practicing physicians for education. These educational classes are conducted by nurses and nutritionists who have been specially trained in diabetes. We have a series of lectures given by a doctor not in practice, a health officer who has had considerable training especially in diabetes. We also have a register of diabetic patients, now more than 800 in number, which has been compiled by the practicing physicians referring their patients to us for contact purposes, to get the names of their relatives and for other purposes of education.

We find that we are getting many more than 2 per cent of the relatives of diabetic patients who actually have diabetes. More than 1 per cent of them have not formerly known that they had any signs or symptoms of the disease. In addition to that, we are doing research work on simplified procedures for diagnosis. We are also preparing for the use of the general practitioner and for health departments, valuable, simple educational material.

DR. JOSLIN: Dr. Palmer brought out what has been emphasized by Dr. McCullagh and others today, that the adequate treatment of diabetes, the aggressive treatment of it, results in a smaller number of complications.

QUESTION: Will you discuss the intravenous use of ether in diabetic gangrene?

DR. PALMER: I know Dr. Katz of New Orleans, and I know he is enthusiastic about it. I have talked to many men who have used it. If one can follow the patients, it is a temporizing measure and may be helpful. I would not condemn it, and I do not encourage its extensive use.

QUESTION: Do you use heat or cold in wet diabetic gangrene, while using antibiotics before resorting to surgery?

DR. PALMER: You should be careful of heat in all cases of diabetes. In the past we have used more heat than at present. I think we try to maintain not cold temperatures. I do not apply refrigeration at all in the attempt to control sepsis from an extremity, unless I were going to use that as the anesthetic.

DR. PALMER: We have used considerable rutin. I cannot be too enthusiastic about it; it is all right to use it.

DR. JOSLIN: About the rutin, Dr. Dodger recently, in his careful article in *THE JOURNAL*, was rather pessimistic. I think our group is not so pessimistic as that. They are rather open-minded. Dr. White feels that with the children who have used rutin the progress of the disease in the eyes has been less rapid. I would like Dr. Wilder to say a word on rutin.

DR. WILDER: We have used it on a good many cases, with results that we cannot interpret. There are some cases of untreated retinitis in diabetes that get spontaneously better. Those cases that have gotten better under the administration of rutin may have deceived us. We have at present an impression—it is nothing more or less than a clinician's impression—that some of these cases have been arrested, their progress delayed by the use of rutin. This is exactly the same impression your associates apparently have in Boston.

QUESTION: Do you plan your diets at all as to the content of cholesterol?

DR. RICKETTS: We do not. Perhaps we should but we have not paid much attention to that. One thing that makes me say so is the report from Rabinowitz' laboratory and clinic in Montreal, in which he had patients, some on high cholesterol and some on low cholesterol diets, and the difference between the blood cholesterol in the two groups was slight. I have never been convinced that it was real or important.

QUESTION: Will you kindly repeat your method of determining the amounts of protein, carbohydrate and fat in the diet?

DR. RICKETTS: One gives 1 Gm. of protein per kilogram or approximately that. If the total caloric requirement is 2,000 calories, one gives, then, 75 Gm. of protein to a man weighing 75 Kg. He supplies in that protein 300 calories, 4 times 75. Subtracting 300 from the 2,000, which we allow, leaves 1,700 calories to be supplied in protein and fat. Of this 1,700 calories, 850 ought to come from carbohydrate and 850 ought to come from fat. If the carbohydrate calories are to be 850, that is equivalent to approximately 210 Gm. of carbohydrate in the diet and 850 calories of fat is equivalent, roughly, to 90 Gm. of fat.

QUESTION: Do you feel it necessary to hospitalize a patient while stabilizing on diet and insulin?

DR. RICKETTS: Ordinarily not.

DR. JOSLIN: It seems to me that we are treating more and more in the office, just as the surgeons more and more are doing preliminary work before they send the patients to the hospital. Really, we have to thank the Mayo Clinic for driving that home, because they have all sorts of dining rooms and they have treated many diabetic persons that way. We know that they do save their hospital beds. We learned a great deal.

QUESTION: At what intervals during the day do you do a quantitative determination of sugar in the urine?

DR. WILDER: In our clinic we do quantitative tests only on twenty-four hour collections and that infrequently. We feel the qualitative test is sufficient for fractions during the day.

QUESTION: How would you aggressively treat a patient with mild diabetes who has a fasting blood sugar of 130 to 140 mg., with no symptoms?

DR. WILDER: It would depend a good deal on the patient, of course. If it is an overweight person, probably the best treatment for him would be a diet without any insulin at all. He probably can be treated with diet, without any insulin, under any circumstances. If it is an early case, I would be much more inclined to be rigid in my management than if it is a later case, because the earlier cases are the cases in which a rigid management can be expected to do some good. After diabetes has lasted two or three years, it has reached a degree of severity that it is likely to continue from then on throughout life. It will be aggravated by infections but it will come back after the infection is over to about the degree of severity it had before. It was just before I left home that I saw a woman who has had diabetes thirty years. She was 50 years old, was only 20 when it started. Our patients starting diabetes at 20, with the typical triad of symptoms, nearly all require insulin. This woman had not used insulin all her life; she had had diabetes thirty years and still was what we call a grade 2 diabetic. When she overstepped the diet, her blood sugar went up to 300 to 400 mg. When on careful diet, she was all right.

Special Article

CANCER OF KIDNEYS, ADRENALS AND TESTES

GEORGE F. CAHILL, M.D.

NEW YORK

This article is the sixteenth and last of a series to be published by the American Medical Association in cooperation with the American Cancer Society. The series is designed to aid in the early diagnosis of cancer and thereby to gain more effective results in treatment.

CANCER OF THE KIDNEY

In two periods of life cancer of the kidney occurs, in infancy and in aging adult life. In infancy occurs one of the more frequent cancers of childhood, Wilms' tumor or infantile embryoma. This is a silent tumor and is highly malignant, with a serious and impressive record of fatal termination. More frequently, there occur in middle-aged or in elderly persons the various epithelial carcinomas of the kidney which are often silent until they reach considerable size and usually show their presence by blood in the urine. The early recognition of renal cancer in both these age groups is a problem for the medical practitioner, because by early surgical removal of the affected kidney lies the correction of an otherwise fatal course of the disease.

Carcinoma of the kidney ranks third in frequency among the tumors of the urogenital system, following carcinoma of the bladder and of the prostate. A few rare tumors of the kidney, not epithelial in origin, such as fibrosarcoma and leiomyosarcoma arise from the renal capsule or pericapsular tissues. The usual cancer is one epithelial in origin, originating from the renal parenchyma or from the epithelial lining of the pelvis. The latter, a specialized epithelium, is in the lining of the ureter and bladder, and all the tumors arising from this specialized epithelium are of similar class, whether from renal pelvis, ureter or bladder. The tumors occurring from the renal parenchyma itself are specific tumors of that tissue.

The formation of the renal parenchyma is of two origins: (1) the part formed from the renal blastema is that part above the "connecting piece" in the system of Henle and (2) the portion below the connecting piece is from the wolffian system and actually is of the same embryologic origin as are the renal pelvis and the ureter. The separate origin of the two parts of the renal parenchyma would lead one to suspect that two different types of tumor cells would occur. Two different types of tumor cells do occur, one a clear cell and the other a granular cell. One or the other may be the predominant cell in a tumor, or sometimes a part may be of clear cells and another part of granular cells. There is, however, as yet no acceptable evidence as to the origin of either the clear cell or the granular cell except that they both are undoubtedly of renal origin. It is also true that clear cell carcinomas occur more frequently in the cortical areas and granular cell tumors more often in the medullary and corticomedullary areas. The clear cell carcinoma may originate from the renal blastema cell; its growth action to some degree suggests such origin, and the granular cell arising from the wolffian system resembles the infiltrating carcinoma of that system.

Small cortical adenomas of the kidney, entirely symptomless, are not infrequently found at operation or at autopsy. These small encapsulated adenomas are considered benign; they may be microscopic in size, and whether they play any part in the production of carcinoma of the kidney is uncertain.

The classification of renal tumors like tumors elsewhere has at times little agreement between clinicians and pathologists. Two recent studies of large series, one by Fite¹ and the other by Melicow,² have considerable classification in common. First, pathologists agree that most renal tumors are renal in origin and that the old term "hypernephroma" if used should be reserved for that small class of adrenal rest tumors.

The following simple classification of renal parenchymal tumors has been found most useful: (a) clear cell carcinoma; (b) granular-cell carcinoma (some tumors occur in which both types of cells occur without evidence as to which one was primary or secondary); both types of cell tumors may show alveolar, adenomatous, tubular, papillary or cystic formations, which are normal or abnormal anatomic architectural arrangements of renal cells; (c) true hypernephroma (adrenal rests); (d) tumors in solitary cysts; (e) multiple papillary adenoma or carcinoma in sclerotic tubular cysts, and (f) mixed forms, among which the carcinosarcoma of infants (Wilms' tumor) is the most frequent.

PARENCHYMAL RENAL CARCINOMA

Parenchymal renal carcinoma is a disease of middle age. In 182 successive cases it occurred in the following ages: 20 to 30 years, twice; 30 to 40 years, sixteen times; 40 to 50 years, forty-two times; 50 to 60 years, sixty-four times; 60 to 70 years, thirty-eight times, and 70 to 80 years, twenty times.

Carcinoma of the kidney occurs more frequently in the male, in the ratio of 3 to 1. In females when tumor occurs it has been most often subsequent to the menopause. The carcinoma occurs about equally on both sides, but has been more frequently operated upon on the right side. Inoperable tumors, due to size fixation or with metastases, occur more frequently on the left side. In the 182 cases mentioned, no operation having been performed because of pulmonary metastases in 24 cases, there were 20 cases with tumor of the left kidney and only 4 with right-sided tumor. A plausible reason assigned was that the deeper situation of the left kidney was more often associated with delayed recognition of the disease, as well as the fact that hematuria occurred more often with right-sided tumors than it did with tumors of the left kidney. Bilateral tumors are rare, occurring once in about 100 cases.

Symptoms.—The symptoms of parenchymal renal carcinoma are a triad of hematuria, pain in the flank and a mass in the flank.

Hematuria occurs in over 70 or 80 per cent of the cases; it presumes a vascular rupture in a well developed neoplasm and should be a late symptom of tumor growth. It is the most frequent and the most important symptom. It may be entirely painless, and sudden in its appearance, and it may spontaneously disappear, or the bleeding

1. Fite, G. L.: Classification of Tumors of the Kidney, Arch. Path. 39:37, (Jan.) 1945.

2. Melicow, M. M.: Classification of Renal Neoplasms: A Clinical and Pathological Study Based on One Hundred and Ninety Nine Cases, J. Urol. 51:333, 1944.

may last a variable time, then cease, and may or may not recur later. At times it may be associated with renal colic, and the patient may pass blood clots. The clots may be like ureter casts. The bleeding is apt to be total and the same throughout the urine until it ceases, to recur later. In some cases the bleeding may persist until corrected by surgery. There is nothing specific about the hematuria that separates renal bleeding from ureteral or vesical.

Pain may occur as a dull ache in the flank. It may be associated with hematuria. At times it may be severe, typical of renal colic, and then definitely associated with passage of blood clots. Continuous fixed pain in flank or back may be a symptom seen with large tumors.

A mass in the loin or a palpable mass in the renal region is frequently found at the time of the appearance of the hematuria. In almost 10 per cent of the cases the patient is conscious of the mass himself. In over 60 per cent of the cases presenting with hematuria, a renal mass was palpable on the first examination. This usually is felt bimanually and is associated on palpation with deep inspiration.

The three symptoms hematuria, pain in the flank and a palpable mass in the flank are frequently the only symptoms present in the early onset. Other symptoms may then follow. Urinary difficulties may arise due to a blood clot in the bladder, and since most of the patients are elderly men, coexistent prostatic hypertrophy may be present with urinary frequency and lessened stream.

Weakness and loss of weight become more frequent as the disease progresses. Often the weakness is present as an only symptom, and at times it seems to be directly associated with the specific tumor and not with metastases, as the weakness syndrome often disappears a few days after the tumor is removed surgically. Fever is not infrequently seen with renal carcinoma. In a few cases unexplained fever was the only presenting symptom. When fever occurs it has been attributed to intratumor hemorrhage and subsequent necrosis, and later often in such cases calcified deposits in the tumor are seen in roentgenograms.

When metastases occur, the symptoms are referable to the organ involved. Rarely the first symptom may be that of metastases. This may be seen with spontaneous fracture of a long bone or the finding of metastases in the lung by roentgen ray. Metastases are found in about 30 per cent of the cases when first seen on admission. About 50 per cent of these are seen in the lungs; about 20 per cent are in the bones. Metastases occur next in frequency in the liver and in the brain.

CLEAR CELL CARCINOMA

The clear cell carcinoma, the most frequent type of tumor seen, was formerly described as hypernephroma by Grawitz, and was supposed to be an adrenal tumor, but it is now generally accepted that it is entirely renal in origin. This tumor grows slowly, may or may not be partially encapsulated, projects as a mass out from the cortex or intrudes on the pelvis. The tumor is soft, with large spherical masses, yellow in color, vascular within and without the tumor, and it may remain local, growing slowly for a variable length of time. Years may pass before the tumor breaks through its barriers and spreads. When it does it may spread locally through the capsule or may form large thrombotic masses which protrude into the veins, at times into

the renal vein and vena cava, and which then appear as spherical metastases in the lungs. The most usual place of metastases with clear cell carcinoma has been in the capillaries of the lungs. This tumor also has a "selective tendency" to metastases

FIG. 1 (M.F.).—A retrograde pyelogram of a clear cell carcinoma of the left kidney. It shows that the tumor mass growing in the upper pole has elongated and twisted the upper calyces and obliterated part and has displaced the renal pelvis and lower part of the kidney downward.

to bone, long bones most often. The clear cell carcinoma is seen among an earlier age group than the granular cell carcinoma.

GRANULAR CELL CARCINOMA

The granular cell carcinoma, the next most frequent type of renal cancer seen, is a more rapidly growing and a more malignant carcinoma than the clear cell. It occurs more frequently in the older age group. It forms a hard solid contracting type of tumor much less vascular than the clear cell but, being more invasive, is more frequently seen with hematuria (80 to 90 per cent) and with pain. This tumor is often stony hard in the kidney and resembles the undifferentiated carcinomas elsewhere, extending by direct extension, by the lymphatics and by the blood stream. Metastatic involvement of preaortic lymph nodes and mediastinal nodes is not infrequently seen early with granular cell carcinoma.

Tumors occur in which both types of cells occur, a mixed cell type. Part of the tumor will be of large soft yellowish masses, but other portions will be hard, nodular and fixed. Examination will show clear cells in one and granular in the other. There has been no evidence as to which type may have been the primary, but these tumors in progress and in seriousness resemble more the granular cell tumor than the less malignant clear cell tumor.

From a consecutive series of 100 cases of all types of parenchymal tumors, the following symptoms occurred: hematuria, 85 cases; loss of weight, 60 cases; intermittent pain in the flank, 30 cases; fixed pain in the back, 22 cases; a palpable tumor (noted by the examiner), 46 cases; a mass as a complaint, 8 cases; weakness or fatigue, 22 cases; difficulties in voiding urine, 12 cases, and fever, 9 cases.

The finding of varicocele on the same side is not infrequent. If pronounced, it is often found to be

associated with an obstructive thrombotic tumor mass in the renal vein.

DIAGNOSIS

It is now an accepted axiom that all cases of hematuria require a urologic investigation as to the source of the hematuria and its cause. Since

Fig. 2 (M.G.).—Retrograde pyelograms in a case of granular cell carcinoma of the kidney, showing contraction of the hard dense renal tumor so that the calyces are almost completely closed. The renal tissue also shows a denser shadow than normal.

the widespread use of intravenous pyelographic mediums, a recognition of the alterations of renal anatomy and physiology suggestive of tumor is more definitely widespread. However, experience has shown most urologists that useful as are intravenous secretory pyelograms, they do not offer the criteria obtained by cystoscopy and retrograde pyelograms. Thus in all cases of hematuria, unless the cause is definitely ascertained by ordinary roentgenograms or intravenous urograms, and if a tumor is suspected, there should be a complete cystoscopic examination. The cystoscopy done at the time of hematuria establishes the site of the lesion, the secretory change on the suspected side compared with the normal, or the proof that the opposite kidney functions normally. The retrograde pyelograms give clearer delineations of the internal architecture of the renal system, far superior to secretory urograms. Often when a tumor is present, with destruction of the renal parenchyma there are insufficient secretory mediums into the pelves and calyces for an interpretive pyelogram with secretory mediums.

Studies of the pyelograms with the types of renal carcinoma have shown the various changes. Large tumor shadows are seen with elongated, narrowed and in other places dilated spidery-shaped calyces spreading beyond a normal renal area; these are characteristic of the clear cell carcinoma. The shadows at times resemble those seen in the pelves and calyces when the kidneys are polycystic. Some resemble the shadows seen with solitary or simple cysts and, since these are often unilateral, may make a specific diagnosis difficult. Narrowing or obliteration of the calyces as shown by the roentgenograms—in fact, in some cases complete disappearance of calycine shadows, with only a compressed pelvic

shadow present, are the appearances associated with the granular cell type of carcinoma. In some cases there appear areas of the large spreading spidery calyces, and in others the obliterated or pinched calyces; this type of roentgenogram is more often seen with the mixed type of tumor. Studies made of kidneys after removal support the interpretive diagnosis in large series of these cases. Hemorrhage is not infrequent within the tumors themselves, and with subsequent necrosis there are deposits of calcified material at various parts of the tumors, so that calcified areas, either small or large, are present in about 25 per cent of the cases and are shown by roentgenograms.

Cytologic examination of the urine is of importance in these cases, as has been stressed by Papanicolaou.³ This may be of the gross urine or may be of material from the ureteral specimens. The examination in which the sediment is fixed and mounted as tissue requires experience as to interpretation because of the changes occurring in the cells which are due to immersion in the urine. In parenchymal tumors, two types of cells are seen: (1) unusually large cells with irregular or multiple nuclei, especially cells with mitotic changes and (2) vacuolated cells with clear cytoplasm, rich in lipids, so characteristic of clear-celled carcinoma (hypernephroma). With experienced observers the high proportion of cases in which these cells are found and the accuracy of their diagnosis are astounding. The use of cytologic studies in all urinary tumors is an essential step, particularly when diagnosis is difficult.

THERAPY OF PARENCHYMAL CARCINOMA

Early surgical removal of the involved kidney and capsule is the only known corrective procedure for renal parenchymal carcinoma. Although recession in size of some renal carcinomas has been reported as a result of roentgen therapy, the resistance of these cancers to roentgen therapy is well known, and any temporary recession of the tumor mass is largely the effect of the radiation on the smaller blood vessels. Because such radiation takes a number of weeks to administer and its effect may be doubtful, preoperative radiation is not widely used for renal carcinoma. In addition, there is difficulty in wound healing and a higher proportion of wound disruption following the operation. These in themselves would not be insurmountable difficulties if there were assurance of the effectiveness of the radiation on the tumor cells, but any effect with the radiation at present administered is questionable. With absence of demonstrable metastases, all renal tumors should, if possible, be completely extirpated as soon as recognized. The major difficulty lies in earlier recognition. Even with questionable metastases, removal still offers the only possible chance with the therapeutic agents now at hand. The size of the tumor mass is no contraindication; although size may be an indication of the duration of a tumor, it is not a definite indication of its activity. Often large tumors may be of low grade malignancy and of slow extension. Theoretically ligation and division of the renal vessels are the ideal first steps in surgical removal of a tumor. This may be more simply accomplished by transperitoneal approach. It may also be done effectively through the flank. The

3. Papanicolaou, G. N.: *New Procedure for Staining Vaginal Smears*, Science 95: 438, 1942; Tr. Am. A. Genito-Urin. Surgeons 33: 147, 1946.

approach, whether flank or abdominal, should be large, much larger than the tumor, so that after ligation and severance of the vessels, the tumor, kidney and perinephritic fascia may be removed en masse with a minimum of trauma. Since parenchymal tumors rarely, if ever, metastasize down the ureter, it is only necessary to remove the accessible portion. Examination of the removed organ will often show extension of tumor into minor or major veins; hence handling of the mass should be at a minimum and severance of the blood vessels should be the first step. Tumor masses may extend into the renal vein and vena cava. Such should be removed from these vessels with resection after removal, experience having shown that at times tumors do not recur in such cases. Retroperitoneal masses of lymph node involvement may be present. These are more frequently seen with the granular cell and mixed cell tumors and are usually discovered after the renal tumor mass is removed. When these nodes are found they may be removed, but rarely has it been possible to do so completely.

PROGNOSIS AND RESULTS

The clear cell renal carcinomas have a much higher percentage of freedom from recurrences than do the granular or mixed tumors. The clear cell tumors, even though of large size, when removed without dissemination show in the various clinics a freedom from recurrence over a five year period varying from 25 to 50 per cent. The freedom from recurrence with the granular cell tumors is much lower, varying from 5 to 10 per cent. Cases of demonstrable metastases treated by roentgen rays without nephrectomy or after nephrectomy show an extremely low survival rate; most patients do not survive a year. Rarely a solitary metastasis may occur and be successfully removed with a good survival rate. Even solitary pulmonary metastases have been successfully removed in clear cell carcinomas with apparently no further recurrence. Improvement in the figures of recurrence is occurring largely as a result of earlier recognition of the disease and widespread improvement in diagnostic procedures. Earlier investigation of those with suggestive symptoms is necessary because even in the most accessible clinics symptoms are present at least a year on the average before the diagnosis is made. It will be interesting to observe the effect of the establishment of the cytologic test of a urinary smear as advocated by Papanicolaou in the routine of laboratories, in the hope that these cases will be reached by therapy earlier in the disease, for therein lies the path of improvement.

CANCER OF THE RENAL PELVIS

Carcinoma of the renal pelvis, arising from the specialized epithelial lining, is the same as the epithelial cancers of the ureter and the bladder. They are less frequent than parenchymal tumor, occurring in the Squier Clinic in a ratio of 1 to 8 (22 to 160). They occur in both sexes, slightly more frequently in males, and occur equally in either kidney. They are more apt to occur in the elderly age group. The decades are 30 to 40 years, 1 case; 40 to 50 years, 3 cases; 50 to 60 years, 7 cases; 60 to 70 years, 6 cases, and 70 to 80 years, 5 cases.

Recognizable etiologic factors may have some influence on the formation of this tumor. Certain aniline dyes with carcinogenic factors have been known to produce these tumors, both clinically

and experimentally. The linking of these carcinogenic agents with the large number of this type of tumors seen is rare at present because known exposure is rare among the patients seen. Pelvic tumors have been reported as associated with pelvic calculi and with long-standing inflammatory processes. Many authors have emphasized the dangers of neglecting calculi and long-standing infections in the kidney. There does not seem to be any recognizable association with congenital abnormalities themselves in the development of pelvic tumors.

The types of tumors of the pelvis are similar to those of the ureter and bladder. They occur from the specialized epithelium of mesodermal origin. They are classified as (1) papilloma, (2) papillary carcinoma, (3) squamous cell carcinoma and (4) undifferentiated carcinoma.

About 50 to 70 per cent of all tumors of the renal pelvis are papillary. They may be single or multiple and are villous or wartlike growths similar to those

Fig. 3 (J.I.).—An intravenous pyelogram of a papillary carcinoma of the pelvis of the right kidney. The irregular less dense shadow is seen surrounded by the denser iodide in the urine in the pelvis.

found in the bladder. They may be small or extensive and may be associated with similar tumors in the ureter or the bladder. They are rarely bilateral. These papillary tumors when seen have a higher percentage of malignancy than tumors of the bladder; over 50 per cent of the papillary tumors occurring in the renal pelvis show malignant tendencies. Microscopically the structure of the papilloma is simple and uniform; it consists of a series of branching connective tissue stromas covered with layers of transitional epithelium. When cancerous, they are more compact with invasion of the submucous tissue and with alteration of cell division and abundance of mitoses; the cells break through the basement membranes. Not infrequently encrustations of urine occur with necrosis of the tumor.

Squamous cell carcinoma in the pelvis is less frequent than the papillary type. It occurs with irritant lesions such as infection, calculus, ureteritis cystica and leukoplakia. The microscopic sections show epidermization and formation of many epithelial pearls. Ulceration is not uncommon, and these tumors are less vascular than the papillary tumors.

Infiltrating undifferentiated carcinoma occurs but

is infrequent. It has the same characteristics as the similar tumors of the bladder; invasion, infiltration, destruction and extension. Tumors of the renal pelvis of papillary type frequently metastasize down the ureter as well as through the lymphatics. Carcinoma most frequently metastasizes through the lymphatics of the renal pedicle and the retroperitoneal nodes. They both then disseminate widely to the lungs, liver, adrenal glands and bones.

Symptoms.—The most outstanding symptom of tumor of the renal pelvis is hematuria. Among 22 cases at the Squier Clinic, hematuria at some time or other occurred in all cases. Other writers have a smaller percentage, but the fact is that this is by far the most outstanding symptom, and it may be the only one. Pain may occur but is not constant nor frequent. If the bleeding is profuse there may be renal colic. If obstruction of the pelvis occurs there may be pain in the flank similar to colic in hydronephrosis. As a rule, however, pain is an infrequent symptom of pelvic tumors.

In only a small number of cases does a palpable tumor mass develop; a concomitant hydronephrosis is the cause of the mass, and this may be relieved by the passage of obstructing material. General symptoms, such as loss of weight, strength and appetite, appear only late in the disease. Vesical symptoms of burning, frequency and dysuria may be present if there is an associated infection.

Diagnosis.—There are no symptoms that are diagnostic of tumor of the renal pelvis. In a case of hematuria and with a complete investigation with cystoscopy and retrograde pyelograms, the condition can be recognized. The defect shadows in papillary tumors may be definitely diagnostic. Not infrequently, obstruction of the ureter may occur, especially with squamous cell carcinoma, and the obstructing lesion produces a characteristic shadow in the retrograde pyelographic mediums. It is in this condition that cytologic urinary studies are often of great value. Not infrequently small pieces of tumor tissue may be passed in the urine which if recognized and examined will definitely establish the diagnosis. In others, sedimentation of the cells in the urine and fixation, mounting and staining may lead to the identification of villous fragments with epithelial cells characteristic of the papillary tumors of the pelvis.

Therapy and Prognosis.—Because pelvic tumors, especially of the papillary variety, are often associated with or followed by similar tumors in the lower part of the ureter, the operative procedure is complete ureteronephrectomy. The usual procedure is a flank or abdominal nephrectomy and the removal of the lower part of the ureter and the cuff of bladder by an extraperitoneal approach in the pelvis through the lower part of the abdomen. The immediate operative mortality of the combined operation is less than 2 per cent in some clinics.

With papillary tumors of the pelvis the prognosis is good. The metastases outside of the urinary tract occur late, and with an early removal this type of tumor gives the best prognosis of all renal tumors. If retroperitoneal metastases have occurred, as they may, though infrequently seen at the time of operation, the prognosis is bad because they are rather resistant to radiation. It seems the bleeding of these papillary tumors occurs early, and as a result these cases are not infrequently seen early. Occasionally a resection of the pelvis with the tumor as the center of

the resected area may be necessary when the kidney is solitary; this has been followed without recurrence.

The squamous cell tumor of the pelvis and the undifferentiated carcinoma offer a poor prognosis. They both have invasive tendencies from the onset, may not present diagnosing symptoms for some time. At operation, extension of the tumor into the kidney itself and to the retroperitoneal nodes is usually found. It is in this latter type because of the exfoliation that studies in uterine cytology, like the vaginal fluid studies in uterine carcinoma, may offer an earlier diagnosis.

EMBRYOMAS OF CHILDHOOD (WILMS)

Embryonal carcinosarcoma, or Wilms' tumor of the kidney, is one of the more frequent carcinomas of childhood, an age in which cancer is rare but extremely malignant. It is a disease of infancy, the great majority of cases occurring before 2 years of age. More than 80 per cent of the reported cases occur before the seventh year. Rarely they may occur in adult life, and are then apparently less malignant. They are found in both sexes in about equal numbers and occur with about the same frequency in both kidneys. The tumors may be bilateral. They usually are not associated with external genitourinary malformations. It has often been reported that the children in whom these tumors occur are among the more comely children seen. Although occasionally trauma has been suggested as being associated with the tumor, there is no evidence or reason to believe that it plays any part in the production of the tumor.

These tumors may arise from any portion of the kidney. They may be in either pole or pelvic area and sometimes may be extrarenal. The tumors expand as they grow and may compress or surround the normal renal tissue. They are most frequently covered by the renal capsule, and grow rapidly with large round or lobular masses, most usually in the line of least resistance forward into the abdominal cavity. They may develop cysts within themselves and sometimes increase rapidly in size because of hemorrhage within the cysts. The microscopic picture is of embryonic renal elements with isolated tubules and glomeruli among the cancerous tissue, the appearance of giant cells and various epithelial cancer cells scattered among or co-existing with areas of sarcomatous tissue. Striated and non-striated muscle cells may occur as well as other cancerous tissue structures.

These tumors are usually rapid growing. However, they apparently remain within the renal capsule for a considerable period, growing only locally and then later metastasizing. The metastases apparently are most often through the blood stream to the lungs and to the liver. Lymph metastases may occur to retroperitoneal and mediastinal nodes. Involvement of the skeletal system is not frequent. At times the tumor may grow directly through the capsule and involve adjacent organs. It is thought that metastases may be precipitated by rough handling of the tumor during examinations.

Symptoms.—There are no symptoms of Wilms' tumor in its early stage; no pain, no tenderness and usually no hematuria. The usual suspicion of its presence is when a mass is discovered in the abdomen or flank, or the size of the child's abdomen draws the attention of the mother or some other observer to the change. Hematuria is infrequent, occurring in less than 10 per cent of the

cases. Pallor, weakness and loss of weight may be present with or precede the finding of the abdominal mass, and they always are present late in the disease. Fever is not of infrequent occurrence and when present may be due to tumor necrosis

Fig. 4 (J.G.).—An intravenous pyelogram in a child with a large Wilms tumor of the right kidney. The left kidney is normal. The right shows a mass above which has displaced calyces laterally and obstructed them. The psoas line is obliterated on that side.

or to hemorrhage within the tumor. Urinary symptoms are usually absent; only occasionally may there be dysuria associated with the clots of the rare hematuria.

Diagnosis.—The diagnosis is made by noting a mass in an infant's loin or side of the abdomen. This mass is usually large, not tender, easily palpable, ballotable through the flank, rounded or lobular and the transverse colon may be anterior to the mass if it is the left kidney. The mass may or may not be fixed in the flank. If it feels lobular or cystic, the lobules cannot be transilluminated. Other conditions which may give a similar picture are conditions which are diagnosed by similar procedures. The various other conditions presenting a similar picture are carcinoma of the adrenal gland (sympathicoblastoma), chronic cystic fibrosis of the kidney, congenital obstructive hydronephrosis, congenital polycystic disease of the kidneys and the retroperitoneal sarcomas of childhood.

In all these conditions, including Wilms' tumor, urologic investigating procedures are absolutely necessary as soon as a mass is felt or suspected. Ordinary roentgenograms of the abdomen may show the mass in the flank and at times some calcification. As a rule little information is obtained from simple roentgenograms of the abdomen, and usually intravenous or subcutaneous secretory pyelograms are also done. If Wilms' tumor is present there is usually the normal secreting and anatomic kidney on one side and there may be diminished secretion on the affected side or calyceal or pelvic distortion as a contrast. At times the calyces may be displaced far from the pelvis. In large tumors there may be no or insufficient pyelographic mediums secreted by the kidney and cystoscopy with retrograde pyelograms may be needed

to show the calyceal and pelvic distortion and loss of renal function, both due to tumor growth. Tumor cells may be found in the urine, but this is infrequent with Wilms' embryoma. The main roentgen observation is the shadows suggestive of changes in the renal parenchyma. These are entirely different from the normal but displaced pyelographic shadow seen with adrenal sympathicoblastoma, from the large reservoir of pelvis and calyces seen with hydronephrosis, from the complete absence of pelvis or calyces and function with chronic cystic fibrosis, from the spidery bilateral changes with congenital polycystic disease and from the normal renal pyelographic shadow seen with retroperitoneal sarcoma.

Treatment and Prognosis.—The embryonal tumors of the kidney are among the most malignant of all renal growths. Their growth at times is extraordinary, and in a large number of cases death will occur in less than a year. In early recognition and in early therapy lies the hope for patients with these tumors. For a long time surgical treatment was considered to be hopeless in these cases, and high voltage roentgen therapy was considered to offer the better prognosis. At the same time and subsequently roentgen therapy was used to bring about a decrease in size of the tumor, to be followed by nephrectomy.

Due to the work of Ladd and his confreres,⁴ at the Boston Children's Hospital a more serious study has been made of the removal of these tumors by the transperitoneal route with a minimum of handling either for diagnostic purposes or on the operating table, with ligation of the renal vessels and pedicle before displacement of the kidney and tumor. The result has been a much higher proportion of these cases free from recurrence than has formerly been reported. Similar reports have been issued from other clinics which show that better results may be obtained by earlier recognition of the tumor, avoidance of trauma by manipulation and earlier and more complete surgical treatment without trauma or dissemination of the tumor. According to reports at times complete disappearance of the tumor mass and freedom from recurrence follow high voltage roentgen therapy. Though this result is unusual, high voltage roentgen therapy is an essential therapeutic agent in cases in which pulmonary or other metastases demonstrated at time of diagnosis make surgical removal of the tumor unwise. The prognosis in these cases will be improved by the combination of early recognition of the condition and better surgical relief.

Wilms' tumors occur occasionally in adults, 53 cases having been collected from the literature by Esersky, Saffer, Panoff and Jacobi.⁵ They have been reported in the seventh and ninth decades but are more frequent from 30 to 60 years. A mass in the abdomen is the usual symptom. The triad of hematuria, pain and mass is not always evident. Fever is frequent. The pyelographic studies show renal changes consisting in growth of a mass. Operative removal has been accomplished. Prognosis is poor even with postoperative radiation therapy, probably poorer than in infants.

LIPOGRANULOMA OF THE PERITONEUM

Report of Three Cases Following the Intra-Abdominal Use of Liquid Petrolatum

WILLIAM G. WHITAKER Jr., M.D.
E. THAYER WALKER, M.D.
and
JOSEPH CANIPPELLI, M.D.
Atlanta, Ga.

Many agents have been employed for the prevention of postoperative intra-abdominal adhesions. During the first two decades of this century, sterile oils were frequently introduced into the peritoneal cavity for this purpose. Their use in experimental animals led observers of this period to believe that such substances as wool fat, petrolatum and liquid petrolatum would inhibit the formation of adhesions.¹ These investigators, however, failed to allow sufficient time before sacrificing their animals, and this led to a false impression that sterile oils not only were harmless but would aid in the prevention of postoperative adhesions. It was later demonstrated that petrolatum and liquid petrolatum (Russian mineral oil)

Fig. 1 (case 1).—Roentgenogram showing calcified lipogranuloma.

were intensely irritating to the peritoneum, were slowly absorbed, if at all, and resulted in the formation of granulomas and adhesions.² Norris and Davison, in 1934,³ reported 2 patients, demonstrating the complications that follow the use

of sterile liquid petrolatum in the abdominal cavity. The roentgenographic observations in most of these cases are characterized by calcareous deposits widely distributed throughout the peritoneal cavity, as seen in cases 1 and 2 reported here.

REPORT OF CASES

CASE 1.—Mrs. E. S., white, aged 65, was admitted to Grady Memorial Hospital May 23, 1947, complaining of cramping abdominal pain, vomiting and obstipation of two days'

Fig. 2 (case 1).—Enlargement of roentgenogram showing calcified lipogranuloma.

duration. A supracervical hysterectomy had been performed in 1924. Two years later the patient began to have frequent episodes of colicky abdominal pain due to partial intestinal obstruction. During the past twenty years she had been seen frequently in the outpatient department with similar complaints.

Examination revealed moderate generalized distention and tenderness of the abdomen. Frequent peristaltic rushes were heard on auscultation, and an occasional visible peristaltic wave was observed. There was considerable induration in both vaginal fornices.

Roentgenographic examination of the abdomen showed numerous cystic calcific structures distributed throughout the abdomen, without significant arrangement in their distribution (figs. 1 and 2). Many of these structures were circular in contour; some had a mulberry-like appearance and others a serrated silhouette. They varied in diameter from 1 to 3 cm. The psoas and kidney shadows appeared normal. Several loops of distended small intestine were observed, suggesting the presence of obstruction.

A celiotomy was performed on the day of admission. The peritoneum was seen to be extremely thickened, and the entire peritoneal cavity was obliterated by dense adhesions. There were calcified nodules, varying in size from 0.5 to 3.5 cm., scattered throughout the peritoneal cavity. A loop of dilated small intestine was identified with difficulty, and a blind Witzel-type enterostomy was done. Histologic examination of several nodules showed dense fibrous tissue with metaplastic bone formation and calcification. A foreign body reaction was

represented in some areas by chronic inflammatory cells, large mononuclear phagocytes and foreign body giant cells surrounding large empty spaces. The cytoplasm of both the mononuclear phagocytes and the giant cells showed fairly large vacuoles (figs. 3 and 4). Histologic diagnosis was lipogranuloma.

Fig. 3.—Photomicrograph of biopsy specimen showing lipid vacuoles with surrounding foreign body reaction.

The patient slowly improved following operation and was discharged one month later.

CASE 2.—Mrs. E. B., white, aged 53, was first admitted to Grady Memorial Hospital in 1924, at which time an inflammatory mass involving the right tube and ovary was excised. Sterile liquid petrolatum was placed in the peritoneal cavity. A laparotomy was performed five years later, and a tumor of the left ovary was removed. Examination nine years following the first operation revealed a firm mass that filled the entire pelvis. There were associated symptoms and physical observations consistent with partial obstruction of the small intestine. Dilated loops of small intestine were seen on roentgenographic examination. Multiple firm nodules were palpated through the anterior abdominal wall.

The patient was admitted to the hospital many times for recurrent intestinal obstruction, and eleven years following the first abdominal operation an exploration was performed because of persistent symptoms of intestinal obstruction. Dense multiple adhesions with "numerous metastatic plaques" on the intestinal serosa and parietal peritoneum were observed. An ileostomy was performed. No specimen for biopsy was obtained. In December 1940, a celiotomy was performed because of symptoms of obstruction. A matted mass of peritoneal adhesions was encountered, and the exploration was abandoned after a specimen of a nodule was obtained for biopsy. Histologic examination revealed lipogranuloma of the peritoneum.

This patient was readmitted May 25, 1947, complaining of vomiting, abdominal distention and pain of three days' duration. There was slight abdominal distention; the peristalsis was hypoactive. She was moderately dehydrated. A roentgenogram of the abdomen at the time of admission revealed several loops of distended small intestine and a small amount of gas in the large intestine. Numerous calcareous ringlike densities (figs. 5

and 6), measuring up to 3 cm. in diameter, were seen throughout the abdomen; many were circular or oval in shape, but some had a mulberry-like appearance. These densities were most numerous along the inferior aspect of the diaphragm and in the region of the pelvic inlet. The psoas shadows and the lumbar part of the spine did not show significant pathologic changes.

Treatment was supportive, and a Miller-Abbott tube was passed. The patient became asymptomatic on the second hospital day and was discharged on the fourth day.

CASE 3.—T. H., white, age 68, had liquid petrolatum introduced into his peritoneal cavity in 1927 following an appendectomy. Abdominal exploration was later carried out on two occasions (1928, 1934) for intestinal obstruction. He was admitted to Emory University Hospital Sept. 19, 1947, complaining of pain in the right upper quadrant of the abdomen and intolerance to fatty foods. Cholecystograms demonstrated a nonfunctioning gallbladder. Two large laminated opacities were seen in the right upper quadrant of the abdomen. On September 20, cholecystectomy was attempted, but was abandoned in the presence of a matted mass of leathery adhesions apparently distributed throughout the abdomen. Identification of abdominal viscera was impossible; the gallbladder was neither seen nor felt. Unfortunately, a biopsy specimen of the mass of adhesions was not obtained, but it is believed that the instillation of liquid petrolatum into the peritoneal cavity resulted in the symptoms and the operative observations in this case.

COMMENT

Following the introduction of liquid petrolatum into the peritoneal cavity, there occurs an intensive inflammatory reaction which results in the formation of dense adhesions between the viscera, mesentery and peritoneum.⁴ This complication may

Fig. 4.—Photomicrograph of biopsy specimen showing lipid vacuoles with surrounding foreign body reaction. Calcification is shown in the dark area in the upper portion of the photomicrograph.

require months or even years to develop fully. Late sequelae include widespread formation of grayish yellow nodules. Histologically, the nodules are cystic and are surrounded by fibrous

4. Cruickshank, A.: Paraffinoma of the Peritoneum, *Lancet* 1:46 (Jan. 4) 1941.

tissue which contains many foreign body giant cells. Most of the giant cells are located near large vacuoles which contain the liquid petrolatum. Calcification occurs late and is distributed at various points in the fibrous stroma, being most conspicuous in the periphery of the nodule.

The roentgenographic appearance of lipogranuloma of the peritoneum is characterized by multiple widely distributed calcareous cystlike structures throughout the peritoneal cavity. However, this roentgenographic pattern is not pathognomonic of this condition. Pugh⁵ and Weig and his co-workers⁶ described cases of pseudomyxoma peritonei in which similar calcareous deposits were seen roentgenographically and subsequently observed at operation. Pugh stated, however, that in one of his cases the possibility of parafinoma could not be ruled out, since it was known that some foreign substance had been instilled into the abdomen at the time of a previous operation. Therefore, the differential diagnosis between pseudomyxoma and lipogranuloma can hardly be made on the basis of roentgenographic examination alone. Nevertheless, the recognition of the characteristic calcareous deposits is of great clinical importance, since it indicates in both conditions the presence of extensive peritoneal adhesions.

Calcareous structures in the abdominal cavity result from various factors which must be considered in the differential diagnosis of lipogranuloma. Calcified leiomyomas are usually few in number and possess a more flocculent type of calcification. Echinococcus cysts are limited in number and are more often located in the region of the liver. Usually a large parent

Fig. 5 (case 2).—Roentgenogram showing calcified lipogranuloma.

cyst is present. Opaque biliary and urinary calculi may be identified by proper roentgenographic procedures. Calcified lymph nodes rarely have a cystic appearance. Vascular calcifications are found in typical locations and are frequently

tubular in character. Calcified appendiceal epiplocae may resemble lipogranulomas in individual lesions, but are fewer in number and are freely movable in the abdominal cavity.⁷

SUMMARY

The cases reported here illustrate the intense inflammatory reaction in the peritoneum which may occur after the use of petrolatum and its derivatives in the abdominal cavity. The late development of recurrent obstructive symptoms was com-

Fig. 6 (case 2).—Enlargement of roentgenogram showing calcified lipogranuloma.

mon in these cases. The roentgenographic observation of ovoid calcified bodies throughout the abdominal cavity is particularly significant. Similar roentgenographic observations may occur in pseudomyxoma peritonei. The history of a celiotomy performed during the period when the intraperitoneal use of oils was in vogue should lead one to suspect lipogranuloma peritonei. Tough dense adhesions throughout the abdominal cavity were observed in the 3 cases presented. Surgical intervention for obstructive symptoms in these cases is often hazardous and frequently futile.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement.

AUSTIN SMITH, M.D., Secretary.

CORRECTION

Dr. James F. McCahey of Philadelphia has called attention to an inaccuracy in a former report of the Council on "Untoward Effects of Endocrine Therapy" (J. A. M. A. 125:786-789, 1944) reading:

"In castrate and eunuchoid cases and in the male climacteric, testosterone provides a potent replacement therapy," with a footnote reference to Dr. J. B. Hamilton's article on testis therapy in "Glandular Physiology and Therapy." The reference number should have been placed directly after the words "castrate and eunuchoid cases," since the term "male climacteric" does not appear at any point in the article by Hamilton. The article was cited because of its warning against overstimulation by the use of testosterone replacement therapy.

The Council regrets that this error had escaped its attention. The question of the acceptability of testosterone in the treatment of the so-called male climacteric is being reconsidered by the Council in the light of further experience.

SATURDAY, OCTOBER 2, 1948

WORLD MEDICAL ASSOCIATION

During the week of September 6-12, representatives of some thirty national medical associations met in Geneva to consider problems of current importance to the medical profession. Among the outstanding accomplishments was the elaboration of an inspirational pledge to be taken by young physicians throughout the world. The assembly considered also the development of a bulletin for the World Medical Association. This publication is to appear quarterly under the editorship of Dr. Morris Fishbein. A committee was also established to develop an international series of principles of medical ethics which would be acceptable to the national medical associations of all of the countries concerned. Among other questions given careful consideration was the establishment of suitable liaison with the World Health Organization of the United Nations and with UNESCO. The problems in which these groups may be jointly engaged would include the perfection of abstracting of the important medical literature of the world and the arrangement of international congresses in the field of medicine; also the place of the physician in time of war and the work now in process on the Pharmacopoeia. Significant also were discussions of the standardization of medical education on a high level throughout the world and plans for postgraduate medical education. Through the office of the secretary general, Dr. Louis H. Bauer, reports were made available on the status of the physician in various nations, on war crimes committed by German physicians and on many other subjects.

Most interest during the meeting centered on the adoption of a series of principles governing the provision of medical care under Social Security. Remarkable unanimity developed in the points of view of doctors throughout the world, all of whom were more concerned with the quality of medical service that could be rendered than with a widespread distribution of a low grade of medical care. THE JOURNAL will make available shortly the final text of the principles governing

medical care under Social Security and also the final text of the pledge. These two documents constitute a landmark in medical progress, since they reaffirm the ethical ideals of the physician throughout the world and the common understanding of physicians everywhere as to the factors necessary for competent medical service.

DIETARY LIPIDS IN TUBERCULOSIS

About forty years ago Weigert¹ conducted feeding experiments with inoculated guinea pigs and concluded that the tuberculous process generalized more rapidly in animals fed a strict carbohydrate diet than in control animals receiving an additional liberal amount of milk fat. From this it seemed logical to assume that dietary lipids could produce only beneficial effects in tuberculosis.

Twenty years later this early assumption was challenged by Troteanu,² who administered cod liver oil directly into the stomach of guinea pigs previously inoculated intraperitoneally with bovine tubercle bacilli. The cod liver oil enhanced the progress of the experimental tuberculosis. This result was confirmed by Negre and his associates,³ who found that the ingestion or subcutaneous injection of cod liver oil or olive oil resulted in an enhancement of experimental tuberculosis in both guinea pigs and rabbits. The opposite results were demonstrated with ethyl esters of palmitic, myristic, lauric, arachidic, capric and stearic acid. Given subcutaneously, these lipids retarded the appearance of experimental tuberculous lesions.

It seemed probable therefore that dietary lipids might exert either beneficial or deleterious effect in clinical cases, depending on the type of lipid used. This conclusion was tested by Dubos and Davis,⁴ of the Rockefeller Institute, who studied the growth of *Mycobacterium tuberculosis* in liquid mediums containing a series of fatty acids. They found that capric, lauric, palmitic and myristic acids were inhibitory at dilutions as high as 1:10,000,000. Growth occurred at concentrations as high as 1:100 with stearic, oleic, linoleic or butyric acids.

Tests of the effects of feeding these antituberculous lipids are currently reported by Hedgecock,⁵ of the department of bacteriology of St. Louis University. The lipids were administered to male Swiss albino mice 90 days of age in the form of oleic acid, olive oil, linseed oil or coconut oil. Each of the lipids was mixed with a fat-free, casein-supplemented ration in a concentration of 20 per cent. The four lipid-containing rations together with the nonlipid control ration were each administered to a group of 25 mice. After having

3. Negre, L.: Ann. Inst. Pasteur **49**:319, 1932. Negre, L.; Berthelot, A., and Bretey, L.: Ibid. **59**:457, 1937.

4. Dubos, R. J., and Davis, B. D.: J. Exper. Med. **83**:409, 1946.

5. Hedgecock, L. W.: Proc. Soc. Exper. Biol. & Med. **68**:106 (May) 1948.

been fed these rations for ten days, 5 mice of each group were set aside to serve as dietary controls. Five others were used for chemical analyses of body fat. The remaining 15 animals of each group were each inoculated intravenously with 0.5 mg. of recently isolated *M. tuberculosis*. The large dose was used because mice are known to be highly resistant to experimental tuberculosis.

Animals remaining alive at the end of thirty-seven days were killed with ether. Sections were prepared from the lungs, liver, spleen and kidneys of each animal at the end of the experimental period, and each organ was assayed for tuberculosis. The assay was based on the relative percentage of tissue of each organ involved. Thus: $\pm$ represented about 10 per cent coagulative necrosis, $+$ represented 25 per cent necrosis, and so on to $++++$, in which the pathologic involvement was about 95 per cent of the entire organ.

On this scale the least involvement ($\pm$) was recorded in the group fed coconut oil. With groups fed olive oil, oleic acid or linseed oil, many of the organs showed $+++$ involvement. Study of the weight loss showed that there was a smaller loss of weight and a lower mortality in the coconut oil group than with the group fed the other lipids.

Determinations of the saponification value and iodine value indicated that each dietary lipid was deposited in large amounts in the body fat. Chemical analyses also showed that coconut oil contains about 7 per cent capric, 46 per cent lauric, 19 per cent myristic and 10 per cent palmitic acid, the four acids found by Dubos to be particularly inhibitory to the *in vitro* growth of the tubercle bacillus.

The conclusion was drawn that 20 per cent addition of coconut oil to the routine casein-supplemented ration retards the progress of experimental tuberculosis in mice. An enhanced progress of tuberculosis is caused by the addition of similar amounts of olive oil, linseed oil or oleic acid. A direct application of these findings to clinical medicine, however, has not yet been suggested.

SALICYLATE THERAPY IN RHEUMATIC FEVER

To effect a cure of rheumatic fever, Coburn¹ claims, one of two objectives must be realized. Either the immune response of the host must be modified so that the patient recovers promptly after his first attack or the capacity of the infected micro-organism to elaborate antigen must be inhibited by a chemotherapeutic agent. Since neither of these objectives has yet been realized, one is limited to the suppression of the inflammatory reaction. If salicylate therapy can modify the sterile inflammatory reaction which occurs during activity of the rheumatic process, one might expect this effect to inhibit the development of cardiac disease.

Evaluation of any form of therapy in rheumatic fever, Coburn states, is difficult because about 20 per cent of young adults may be expected to have a monocytic attack and recover spontaneously under symptomatic treatment. About 40 per cent of 43 young adults treated with daily doses of 3 to 6 Gm. of sodium salicylate manifested rheumatic activity for more than one month and showed a definite tendency to contract valvular heart disease, while all of 18 patients treated with daily doses of 10 Gm. or more of sodium salicylate either orally or intravenously showed rapid clinical recovery and a progressive fall in the blood sedimentation rate. Although half of the 18 patients had electrocardiographic evidence of carditis on admission, in none did clinical signs of valvular heart disease develop.

By the method of determination of plasma salicylate concentration, developed by Brodie, Udenfriend and Coburn,² it was found that with the institution of daily oral doses of 10 Gm. of sodium salicylate the plasma level rose in forty-eight hours to between 331 and 454 micrograms per cubic centimeter, with an average maintenance level of 368 micrograms. At this plasma level the sedimentation rate of each patient fell within six days and continued to fall progressively to normal so long as this level was maintained. The induction of a high plasma salicylate level was followed not only by a rapid progressive fall in the blood sedimentation rate but also by a marked and rapid improvement in the clinical appearance.

Twenty patients maintained at 359 to 400 micrograms per cubic centimeter manifested a prompt and progressive subsidence of rheumatic inflammation, while 20 other patients with plasma levels below 250 micrograms per cubic centimeter continued to manifest an active inflammatory process. The intravenous administration of sodium salicylate is required to obtain a rapid rise in the plasma concentration of salicylate to 400 micrograms per cubic centimeter. In none of the 38 rheumatic patients treated with 10 Gm. of sodium salicylate daily did valvular heart disease develop, and in 21 out of 63 similar cases in which only small doses of sodium salicylate were given physical signs of heart disease developed. Coburn feels that a plasma salicylate level of at least 350 micrograms per cubic centimeter may be required to suppress the rheumatic reaction and that plasma level below 200 micrograms per cubic centimeter may be sufficient to relieve symptoms while masking a progressive inflammatory process.

Reid³ treated patients having rheumatic fever with sodium salicylate orally and found that when the average plasma level concentration was less than 20 mg.

2. Brodie, B. B.; Udenfriend, S., and Coburn, A. F.: Determination of Salicylic Acid in Plasma, *J. Pharmacol. & Exper. Therap.* 80: 114-117 (Jan.) 1944.

3. Reid, J.: Does Sodium Salicylate Cure Rheumatic Fever? *Quarterly J. Med.* 17: 139-151 (April) 1948.

per hundred cubic centimeters the erythrocyte sedimentation rate showed no signs of falling; when the level was between 20 and 30 mg. per hundred cubic centimeters a slow fall was observed; when it was between 30 and 40 mg. the rate rapidly returned to normal. He argues that if the erythrocyte sedimentation rate can be accepted as a reliable index of rheumatic activity, then sodium salicylate has a curative action in the disease directly related to the plasma concentration of the drug. This conclusion is strongly supported by the observation that recurrence of the disease during oral treatment with salicylate coincides with pronounced fall in plasma salicylate level and subsequent remission with a secondary rise in the plasma level of the drug. It appears therefore that the main practical problem in the treatment of rheumatic fever is to know when enough salicylate is being given.

Reid concludes that effective treatment of rheumatic fever with salicylate demands that dosage should be controlled by repeated estimations of plasma or urinary salicylate. Cure of the disease depends not only on reaching but also on maintaining a high plasma salicylate level.

While salicylic acid is probably not the final solution to the therapeutic problems of rheumatic fever, with the development of blood level methods other drugs may be found to be more effective in suppressing the rheumatic reaction.

Current Comment

EMPLOYMENT OF THE HANDICAPPED

National Employ the Physically Handicapped Week beginning on October 3 has been set aside by President Truman to call attention to the courageous efforts of many disabled persons and to dramatize the activities of organizations engaged in rehabilitation. Repeated studies and demonstrations have shown that the physically handicapped employee is as dependable and productive as his normal co-worker and in many cases even more so. Reemployment would be more effectively accomplished if physicians understood the vital role that they must play throughout the entire rehabilitation procedure. Reassurance concerning reemployability will do much to prevent traumatic neurosis. Competent medical care of the disabled will aim to restore the injured to his former earning capacity in the same line of work and with minimum loss of time. When there is a residual disability that requires retraining and readjustment, the physician, the rehabilitation counselor and the work supervisor must work together in fitting job requirements to the physical ability. Work itself can be a potent therapeutic force. There is no greater contribution to peace of mind than congenial employment in safe and healthful surroundings. The National Committee in charge of Employ

the Physically Handicapped Week bases its appeal to the public on terms of social and economic necessity. However, employment of the handicapped is not only good economy but also good medicine as well.

SILICOSIS

Silicosis continues to be a baffling problem after decades of study by professional and lay investigators. Patrick Heffernan, who has maintained an interest in this subject for many years,¹ comments² on the statement by Starling that "no substance introduced into protoplasm has any chemical influence on it unless it be soluble." Heffernan feels that the statement is misleading. As evidence, he refers to the "permutite" water softening process, a reaction between a solid and liquid, to the gas mask with the reaction between a solid and gas and, finally, to the more recent demonstration of the atomic architecture of minerals which show lattice structure. Comminution of minerals exposes fractured surfaces on which at numerous points free and unsatisfied valency forces exist whereby water can be attracted and held as water of constitution in the hydrated particle. Freshly powdered quartzite is just such a mineral, carrying powerful free and unsatisfied valency forces avid to take up water and other reactive material at its fractured surfaces. Obviously, when such powder comes in contact with protoplasm, it will hydrate itself at the expense of the fluid content of the protoplasm. The activity of mineral particles with other solids, liquids, or gases falls under four headings: (1) direct combination, (2) hydration, (3) oxidation and (4) hydrolysis. The behavior of dust produced from any rock formation can be estimated usually beforehand from its atomic lattice structure and depends on the existence at the fractured surfaces of free and unsatisfied valency forces. The fractured surfaces of a quartzite particle present a huge negative ion. A broken asbestos fiber can be active only at its fractured extremities, and a sheet of mica can be active, if at all, at its fractured edges only. As the particles become weathered, their activity disappears. Silica dust is more active chemically as a dry aerosol than in any wet vehicle. Heffernan says that the essential agent in the causation of true silicosis, as distinguished from nonspecific pneumoconiosis, is the freshly cloven silica particle. The pathologic process basically consists of the hydration of the silica particle at the expense of the cell protoplasm. Because of its atomic lattice structures, quartzite, when powdered, yields a more virulent dust than other silica formations. Fully hydrated silica—silica hydrosol—sometimes mistakenly called "silicic acid," is nontoxic and enters freely into the metabolism of plants and animals, while partly hydrated suspension of silica in water, "colloidal silica," retains some of the chemical activity of the dry powder but in lesser degree. Thus we progress with the vastly important problem of silicosis. Exact knowledge of its cause will assure more successful control and preventive measures against this health hazard.

Record in Physician-Attended Births

Data released by National Office of Vital Statistics show that 1946 marked a new high record in the matter of physician-attended births and births taking place in hospitals. Of the 3,288,672 live births recorded for the year, 2,708,223 (82.4 per cent) were in hospitals and 402,759 (12.2 per cent) were attended by physicians outside hospitals. Only 177,690 (5.4 per cent) were attended by midwives or other nonmembers of the medical profession. By contrast, in 1935 only 37 per cent of confinements were in hospitals, slightly more than one half were attended by physicians outside hospitals and in 1 out of 8 midwives or other nonprofessional persons were utilized.

The statistical picture reveals significant differences between white and nonwhite groups and between urban and rural areas. All but 1.6 per cent of the white births were attended by physicians, and 87.1 per cent occurred in hospitals. For non-white births, the physician in attendance percentage was 65.2, and only 45.2 per cent took place in hospitals. For city residents, 97.9 per cent had physicians and 92.5 per cent of the births were in hospitals. Corresponding percentages for rural dwellers were 89.6 and 67.1.

Orthopedic Surgeons on New Certification Board

Drs. H. H. Kessler, Atha Thomas and R. H. Alldredge are the three physician members of the first board of directors of the American Board for Certification of the Prosthetic and Orthopedic Appliance Industry. The other four members of the board, all of whom are laymen engaged in the artificial limb industry, are Chester C. Haddan, Denver; David E. Stolpe, New York; Lee J. Fawver, Kansas City, and J. B. Korrady, Chicago. Announcement of the board's election and of Mr. Haddan's election as its president was made in Washington by Glenn E. Jackson, secretary of the committee which arranged for establishment and incorporation of the new American Board. Its function will be to set up standards for certification of qualified limb fitters and of the firms by which they are employed. Approximately 400 of the estimated 575 manufacturers of prosthetic and orthopedic appliances in the United States participated in the mail ballot poll which resulted in approval of the certification plan and election of the four lay members of the directors' board, said Mr. Jackson. The three medical members were unopposed.

Progress in Aviation Medicine

Objectives and accomplishments of the aeromedical and aviation psychologic research programs currently being conducted under technical supervision of the Air Surgeon are described briefly in the U. S. Air Force annual report made public August 22. The 112 page illustrated report cites: development of a flying suit that will enable aircrewmembers to perform their duties with safety and in comfort at 60,000 feet; progress toward perfection of an internally ventilated flying suit that will give the wearer a "temperature tolerance" ranging from minus 60 F. to plus 180 F.; rising emphasis on development of lighter and readily transportable surgical and medical equipment.

"A preliminary proposal for an air-borne hospital utilizing the most recent equipment has been prepared that promises to revolutionize medical field operations in support of air-borne operations," says the report.

"To further medical progress and to meet urgent civilian emergency needs, the Air Force has made much of its specialized equipment available to research institutions and physicians. A number of low-pressure chambers with accessories, for example, have been loaned to American universities, and during the infantile paralysis epidemic of last year Air Force resuscitation apparatus, and even aircraft for emergency evacuation, were utilized for civilian care."

Progress Report on Bone Strength Study

The National Bureau of Standards has published a technical report on the progress of investigations which it is conducting, with cooperation of the Naval Medical Research Institute, on mechanical properties of human bones. Initiation of the research was prompted by military necessity to acquire information which might prove useful in protecting aviation personnel in crashes, seat ejection from aircraft and in parachute openings. Another practical military consideration is the injury frequently caused to sailors when the ship's deck buckles as the result of an explosion, fracture of the os calcis being a common occurrence in such instances.

Initial work in the cooperative study involved seventeen tests on specimens made from compact type bone from extremities of human beings and monkeys. Of the fourteen specimens tested in compression, with the direction of the load parallel to the fibers of the bone, it was demonstrated that their average ultimate strength was about 23,000 pounds per square inch. "These preliminary data," said the report, "indicate that bone may be considered an elastic, brittle material, having about one fourth the compressive strength of cast iron and more than twice that of hickory wood."

"Model" Milk Ordinance

Thirty-four million Americans are now protected through a model milk ordinance whose nationwide adoption was recommended by the U. S. Public Health Service. The estimate was made in conjunction with issuance by the U. S. Public Health Service of a compilation of disease outbreaks in 1946 which were ascribed to milk and milk products. During that year, according to reports forwarded to Washington by state and territorial health authorities, there were twelve such outbreaks. Eleven involved raw milk and the other followed accidental contamination of pasteurized milk by a toxic chemical. There were six other outbreaks in which milk was suspected but not conclusively incriminated. The milk ordinance is now effective in 1,207 municipalities and 207 counties in 39 states. It has been incorporated into state regulations in 31 states, 2 of which enforce compulsory pasteurization.

Navy Reports on Incidence of Phlebitis and Sinusitis

The Navy Department's Bureau of Medicine and Surgery has completed ten year studies on the incidence of phlebitis and sinusitis. Regarding the former, compiled data show that 6,222 cases were reported among Navy and Marine Corps personnel between 1936 and 1945, inclusive, in addition to which there were 1,131 readmissions. The peak was reached in 1945, when 63 out of each 100,000 persons in uniform were on the sick list with phlebitis. During the same decade, sinusitis cases totaled 39,553 for an average incidence rate of 357.5 per 100,000. It was estimated that one eighth of the cases existed prior to entry into military service. The peak year was 1943 (464.4 per 100,000) but beginning in 1944 and continuing to the present rate has declined steadily.

Dr. Robert J. Anderson Heads Public Health Service Tuberculosis Division

Dr. Scheele, Surgeon General of the U. S. Public Health Service, has appointed Dr. Robert J. Anderson as medical director and chief of the Tuberculosis Division. He succeeds Dr. Francis J. Weber, who has been assigned to postgraduate work in psychiatry at Johns Hopkins University. Dr. Anderson formerly was assistant chief of the division.

Information Center on Child Life Research

A new office that will function as a clearing house of information on medical and other types of research relating to children's health and welfare has been set up in the Children's Bureau, Federal Security Agency. Clara E. Council has been appointed director of the unit, which will be under the general supervision of Dr. Martha M. Eliot, associate chief of the Bureau.

GOVERNMENT SERVICES

ARMY

COORDINATE QUARANTINE REGULATIONS

Public health quarantine regulations of the Canal Zone and the United States have been coordinated in a way that will facilitate maritime and air commerce after September 1. As of this date, ships and aircraft receiving complete public health quarantine clearance at a port in one of these areas will not be required to undergo quarantine inspection on arrival at the other area, unless stops are made at a foreign country en route.

Surgeon General Leonard A. Scheele of the U. S. Public Health Service explained that quarantine inspections are performed primarily to prevent importation of the internationally designated "quarantinable diseases": cholera, transmitted by infected food or water or by contact; plague, transmitted by the rat flea or contact; typhus, transmitted by lice; smallpox, transmitted by contact, and yellow fever, transmitted by the *Aedes aegypti* and other mosquitoes. Ships are inspected before being permitted to dock unless specifically exempted. A sanitary inspection is made, and the ship fumigated if a rat colony is found on board. Air travelers are inspected in a quarantine room at the airport before being permitted to come in contact with persons at the place of arrival. During flight from yellow fever areas airplanes are sprayed on the inside to kill mosquitoes, and they may be sprayed again on arrival.

Health officials have declared that under the provisions of revised quarantine regulations the new United States-Canal Zone procedure for exempting ship and aircraft from inspection will be entirely safe with respect to disease control.

THE HOTTEST PLACE IN NORTH AMERICA

A study prepared for presentation to the American Meteorological Society by Arnold Court, meteorologist in the Office of the Quartermaster General in Washington, shows that the hottest place on the North American continent is the surface of the ground in Death Valley in Southeastern California during the month of July. On the basis of averages covering a period of thirty-six years, a maximum temperature of 180 F. may be expected on the desert floor on one day every seven years, while at 5 feet above the ground, where official temperatures are recorded, the reading would be 125 F. Weather observations in Death Valley were begun April 30, 1891, when a temporary weather bureau station was set up on Furnace Creek. In June 1911, a cooperative station of the Weather Bureau was established at Greenland Ranch, 178 feet below sea level, where observations have been taken by the foreman of the Pacific Coast Borax Company once each day ever since, with few exceptions. The highest temperature ever reported for Death Valley, 5 feet above the ground, was on July 10, 1913, when 134 F. was registered; during the week of July 7-14, 1913, the maximum for each day did not fall below 127 F., a record which has not since been equaled. July temperatures show wide spreads between maximum and minimum, and the minimum reported for Greenland Ranch was 68.26 F. in 1938.

THE STERNBERG EXHIBIT

The sixth exhibit in the series, "Famous Men of Army Medicine," currently presented by the Army Medical Museum, is devoted to George Miller Sternberg, Surgeon General of the Army from 1893 to 1902, who, during his distinguished career, was a president of the American Medical Association and of many other scientific societies. Dr. Sternberg is said to have seen more service on the battlefield during the Civil War than any other medical officer. After this period he acquired wide experience in dealing with cholera and yellow fever epidemics, and this led him to take up the study of bacteriology on which much of his fame rests. He was the first in this country to show the organisms of tuberculosis, malaria and cholera, and the first to teach American physicians the fundamental principles and technics of bacteriology. Among many other accomplishments, he was the author of a textbook on bacteriology.

MEDICAL MEETING IN KOREA

On August 11, the Army medical officers stationed in Korea met at the 34th General Hospital and were addressed by Dr. Lenox K. Baker of Duke University College of Medicine, Durham, N. C., who is touring the command as a consultant in orthopedic surgery. Dr. Baker lectured on "Low Back Pain" and made ward rounds. At the afternoon session, Lieut. Col. John J. Marren, commanding officer of the hospital, presided; Dr. Baker discussed Colles' and Pott's fractures; Lieut. Morton Goldman discussed hepatic function tests, and Lieut. Rolf Andreassen presented a case report; Lieut. Duane presented a paper entitled "Fractures and Dislocations of the Spine," which was discussed by Dr. Baker. A picnic supper was held in the evening at the officers' club.

EXTEND TRAINING PROGRAM LIMIT

The Surgeon General's Office announces that the date on which applications may be received from young doctors to take advantage of the Army's graduate training program has been extended to November 1. Under the program, selected medical graduates may serve their internships and residencies in civilian hospitals of their own choice, with first lieutenant's pay, but at the end of their year's training interns must apply for regular Army commissions and may apply for residency training; residents may continue their residency toward specialty qualification. Each, however, is required to serve a year of active duty for each year of training at Army expense.

PERSONAL

The British Ambassador to the United States, Sir Oliver Franks, presented decorations at the British Embassy in July to Dr. John F. Fulton and Brigadier General Edgar E. Hume, both of whom are honorary consultants for the Army Medical Library.

MISCELLANEOUS

COURSES IN RADIOISOTOPES

The Oak Ridge Institute of Nuclear Studies announces that four additional radioisotope courses have been scheduled as follows: October 25 with industrial personnel having priority; Jan. 3, 1949, government personnel; Feb. 14, 1949, medical personnel, and March 14, 1949, general. Thirty-two participants will be accepted in each course, and the four weeks' period will be divided into laboratory work, lectures on laboratory experiments, general background lectures and special topic seminars. Information may be obtained from Dr. Ralph T. Overman, Special Training Division, P. O. Box 117, Oak Ridge, Tenn.

NATIONAL SECURITY RESOURCES BOARD

The following chiefs of sections of the Medical Division of the National Security Resources Board have been appointed, thus virtually completing the staff of the Medical Division: Rear Admiral Thomas Carlyle Anderson, M.C., U. S. N., in charge of the unit dealing with medical and related manpower; Lieutenant Colonel Howard B. Nelson, in charge of planning for health supplies; Vincent B. Lamoureux, in charge of sanitary engineering aspects of national security, and Ruth Freeman, in charge of the division's section on public health nursing.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

Personal.—More than forty doctors of Meriden, Wallingford and Southington joined the Meriden Medical Society, June 16, in paying honor to Dr. Fessenden N. Otis, Meriden, on the occasion of his retirement June 30 from the Meriden Hospital, where for many years he was head of the radiology department. Dr. Otis received an inscribed sterling silver tray showing testimonials of high regard expressed at the meeting.

Postgraduate Education at Yale.—First formal courses of postgraduate education for Connecticut physicians began the last week in September with a course in gastroenterology. The program is sponsored jointly by Yale University and the Connecticut State Medical Society under the direction of Dr. William R. Willard, Assistant Dean of Yale (*THE JOURNAL* April 17, p. 1055). Twelve sessions of two hours each will be devoted to diseases of the gastrointestinal tract and interrelationships with diseases of other organs. This course runs through December 16. An orientation course for part time physician anesthetists will be offered in eight all-day sessions October 11 to November 30. Laboratory and clinical demonstrations and discussions will be conducted from October 13 to December 1. A review of present knowledge and new developments in endocrinology will be given on Wednesdays from 6:30 to 10 p. m., and ten sessions in obstetrical practice will be given between October 5 and December 7. A course in surgical diagnosis will run from September 29 through December 15. Other courses will include orthopedics, demonstrations in anatomy, cardiovascular disease, metabolism, nutrition and diet, infectious diseases, pathology and early diagnosis of cancer.

FLORIDA

Medical Supplement in Newspaper.—The Escambia County Medical Society sponsored an eighteen page medical supplement in the regular Sunday edition of the *Pensacola News-Journal* June 27. A committee from the medical society assembled and edited copy submitted by doctors, nurses, health officials; welfare agencies and others. The cooperation and support of business firms in Pensacola helped make the enterprise possible. Comment on the medical supplement indicates that the reception by the public was favorable. The project was a revival of a successful venture of prewar days.

ILLINOIS

Record Low Infant Mortality.—The Illinois Department of Public Health reports fewer than 18 stillbirths per thousand live births during the first quarter of 1948, an all time low. Record low mortality rates were also recorded for babies under 1 month and for babies under 1 year, 19.2 and 28.9, respectively, per thousand live births. Neonatal mortality was higher among residents of the Southern Region (21 per thousand live births). Lowest neonatal rate was among residents of the Peoria Metropolitan Area, 14 per thousand live births. The death rate for premature births for the entire state is 9.5 for every thousand live births. The highest rate, 10.1 per thousand, was found in the Chicago Metropolitan Area. The maternal death rate for the state, 1.1 per thousand, was exceeded in the Central Area where 1.7 mothers per thousand live births died, and mortality among mothers of newborn babies in the Central Area was over four times as heavy as for mothers in the Northern Area.

Chicago

Public Lecture Series on Tuberculosis.—The Tuberculosis Institute of Chicago and Cook County is presenting a series of seven free lectures on tuberculosis at the Museum of Science and Industry on Sunday afternoons at 3 p. m. The remaining lectures, all by Chicago physicians, will be:

- Oct. 3, Drs. Robert G. Block, Edwin R. Levine and Henry C. Sweany, Round Table Discussion, Treatment of Tuberculosis.
- Oct. 10, J. Edmond Bryant, The Stuns and Tuberculosis.
- Oct. 17, William F. Petersen, Tuberculosis and the Climate.
- Oct. 24, George C. Turner and Dr. Levine, Round Table Discussion, Can Vaccination Control Tuberculosis?
- Oct. 31, Arthur W. Newitt, Tuberculosis Control in Chicago.

Study Recommendations of Health Survey.—Plans for a drive to put into effect the recommendations of the Chicago-Cook County Health Survey completed last year will be the duty of a committee being formed under sponsorship of the Health

Division of the Council of Social Agencies of Chicago. Chairman of the committee is Samuel A. Goldsmith, director of the Jewish Charities. The division is now determining the number of recommendations of the survey that have already been adopted by the governmental and other agencies of the county. When this study is completed, expansion and financing of health departments will be outlined for an intensive campaign throughout the county. The Chicago-Cook County Health Survey was made by the U. S. Public Health Service, at the request of Edward J. Kelly, then mayor, and Clayton F. Smith, then president of the county board. They acted at the suggestion of a committee representing the Council of Social Agencies, the Chicago Medical Society and the Institute of Medicine of Chicago. The reports, forty-one in all, evaluated health facilities of the community and made detailed and practical recommendations for improvement. Major emphasis in the coming campaign is expected to be placed on the expansion of the Chicago Health Department and the Cook County Department of Public Health.

INDIANA

Personal.—Dr. Carl H. McCasky, chairman of the executive committee of the Indiana State Medical Association, presented a paper on "Surgery of the Laryngeal Disease" September 7 before the Pan-Pacific Surgical Association at Honolulu, Hawaii. The association is composed of all countries bordering on the Pacific Ocean.

University News.—Surgical research has been added to the program of the Indiana University School of Medicine, Bloomington-Indianapolis, with the appointment of Dr. Leslie W. Freeman as director of surgical research and the granting of a fellowship in surgery to Dr. Joseph C. Finneran. The program will be under the supervision of Dr. Harris B. Shumacker Jr., professor and chairman of the department of surgery. Dr. Freeman, previously associated with Dr. Shumacker in a similar capacity at Yale University, New Haven, Conn., served as chief of paraplegia services at Vaughan Hospital, Hines, Ill., and at Kennedy General Hospital, Memphis, Tenn., when it was taken over by the Veterans Administration. Dr. Finneran, a graduate of Harvard University, Cambridge, Mass., and Johns Hopkins University School of Medicine, Baltimore, recently completed an internship in surgery at Johns Hopkins Hospital.

MAINE

Research Program of Jackson Memorial Laboratory.—The new plan for organization of the work of the Roscoe B. Jackson Memorial Laboratory appears as part of the annual report released August 27. The first section deals with the laboratory's research program, a twelve month activity, whose objective is to use genetic methods and material as a basis for research in biology and medicine with special emphasis on the growth and development of mammals. This is under the direction of George W. Woolley, Ph.D., the laboratory's assistant director. A supply service to 150 major research laboratories constitutes the second phase of the program. The scientific supervision of this work is under Elizabeth S. Russell, Ph.D., at the main units of the laboratory. Year around cooperation will be maintained with practical breeders of small mammals. The Summer Research Center for Visiting Investigators involves ten weeks or more of activity. This phase of the program affords opportunity for visiting investigators to use special material and techniques available at the laboratory. A second objective is to bring into contact with the resident staff for the exchange of ideas, persons with new and varied points of view and skills. The Training School for Scientific and Medical Students will include year round opportunities for certain students, aside from its ten weeks of intensive summer activity, including those who will work for the doctorate under cooperative agreement with established universities. The trustees have decided to exclude from the Jackson Laboratories all of the radioactive isotopes and all animals and materials exposed to them, but a controlled population of mice will be constantly maintained at the laboratory for staff members wishing to take material to other laboratories for work with isotopes.

MARYLAND

County Society Program.—The Montgomery County Medical Society, meeting on the third Tuesday of each month at the Manor Country Club, Norbeck, has arranged the following programs for the rest of 1948:

- October 19, A. Magruder MacDonald, Washington, D. C., The Duties and Functions of the Coroner's Office.
- November 16, Brian B. Blades, Washington, D. C., Tumors of the Chest.
- December 21, Frank P. Foster, Boston, Diseases of the Thyroid Gland.

MASSACHUSETTS

Dean Burwell Resigns.—Dr. C. Sidney Burwell, dean of Harvard Medical School, Boston, since 1935, has resigned effective Feb. 1, 1949. He will continue actively as research professor of clinical medicine in the medical school and at the Peter Bent Brigham Hospital. Dr. Burwell received his M.D. degree from the Harvard Medical School in 1919. After World War I he spent some time as a member of the American Red Cross Commission in Western Russia. He came to Harvard from Vanderbilt University School of Medicine, Nashville, Tenn., where he had been professor of medicine and physician in chief at the Vanderbilt University Hospital. Earlier he taught and performed research at Harvard and at the John Hopkins Medical School.

Appoint Professor of Psychiatry.—Dr. William Malamud, clinical professor of psychiatry, has been appointed chief of the Boston University School of Medicine's department of psychiatry and psychology, and full time professor of psychiatry, also consultant in psychiatry on the staff of Massachusetts Memorial Hospital and chief of psychiatric service of the outpatient department. Dr. Malamud has been a part time member of the Boston University faculty for eight years and head of the department of psychiatry since 1946. He is chairman of the training committee of the U. S. Public Health Service, Division of Mental Hygiene; chairman of the Committee on Mental Education of the Group for the Advancement of Psychiatry, and counselor of the American Psychological Association. A graduate of McGill University Faculty of Medicine, Montreal, Canada, 1921, Dr. Malamud was associate professor and professor of psychiatry at the University of Iowa from 1929 to 1939. Since then he has served as clinical professor of psychiatry at Boston University School of Medicine and Tufts College Medical School.

MICHIGAN

Gordon Scott Appointed Acting Dean at Wayne University.—Gordon H. Scott, Ph.D., chairman of the department of anatomy at Wayne University College of Medicine, Detroit, has been named acting dean of the college to fill the vacancy left by the resignation of Dr. Hardy A. Kemp (THE JOURNAL, August 14, p. 1474). Dr. Scott joined the Wayne University staff in January 1945, having held a similar chairmanship at the University of Southern California School of Medicine, Los Angeles. He had previously served at the Rockefeller Institute for Medical Research in New York and the Washington University School of Medicine in St. Louis. During World War II he handled work in connection with the government's Office of Scientific Research and Development. He did graduate work at Johns Hopkins University and the University of Minnesota.

Symposium on Protoplasm.—The Detroit Institute of Cancer Research will present a symposium on the Fundamental Properties of Protoplasm October 4-6 on the occasion of the dedication of its laboratories. The scientific session will be held in the Horace H. Rackham Educational Memorial Building. Physicians included on the extensive program are:

Carl F. Cori, St. Louis, Recent Work with Crystalline Enzymes.
Harry S. N. Greene, New Haven, Conn., Biological Assessment of Tissue Potentialities.
F. Peyton Rous, New York, The Natural History of a Cancer.
Charles S. Cameron, New York, The Professional Education Program of the American Cancer Society.
Murry M. Copeland, Washington, D. C., Benign Lesions of the Breast.
Willard M. Allen, St. Louis, Clinical Uses of the Sex Hormones.
Stuart W. Harrington, Rochester, Minn., Malignant Lesions of the Breast.
Douglas Quick, New York, Cancer of the Head and Neck.
Bradley L. Coley, New York, Diagnosis and Treatment of Bone Tumors.
Thomas E. Jones, Cleveland, Carcinoma of the Rectum and Sigmoid.
The clinical program has been arranged by the Cancer Committee of the Wayne County Medical Society and is sponsored by the Education Committee of the American Cancer Society, Southeastern Michigan Division.

NEBRASKA

Form Nebraska Medical Foundation.—The Nebraska Medical Foundation, Inc., was formed recently through the efforts of the Nebraska State Medical Association. The purpose of the foundation is to carry on an effective medical education program in the medical sciences, to further research through providing facilities and training for personnel and, in general, to improve medicine and medical care in Nebraska. Through the work and intensive efforts of Dr. Harold S. Morgan, Lincoln, and his committee, which was authorized in 1948 by the council of the state association, the foundation became a reality.

NEW YORK

Erie County Society Meeting.—The Medical Society of the County of Erie will begin its fall programs with its second Clinical Afternoon and Evening, October 20 at the Hotel Statler, Buffalo. Speakers will be:

George E. Slotkin, Buffalo, Results of the Treatment of Urinary Tract Tuberculosis with Streptomycin and Chaulmoogra Oil.
Gera de Takats, Chicago, Treatment of Cerebral Apoplexy.
Charles D. Marple, New York, Use of Anticoagulants in Thromboembolic Conditions with Particular Reference to Coronary Thrombosis and Myocardial Infarction.
Jere W. Lord Jr., New York, Surgical Treatment of Portal Hypertension.

A subscription dinner in honor of the guest speakers will be served between afternoon and evening sessions. Tickets at \$5 each may be secured from the county society in Buffalo.

New York City

University Appointment.—Dr. William L. Watson, of the thoracic surgical service staff of Memorial Hospital for the Treatment of Cancer and Allied Diseases, was appointed associate professor of surgery at the New York University College of Medicine, August 1.

Bronx Society of Neurology and Psychiatry.—The Bronx Society of Neurology and Psychiatry has recently been incorporated with thirty-six members. Its officers are: Dr. Joshua H. Leiner, president; Dr. Jacob H. Friedman, secretary, and Dr. Moses J. Madonick, treasurer.

Emotional Aspects of Rehabilitation.—Joseph Levi, Ph.D., formerly chief clinical psychologist, Veterans Administration Hospital, Bronx, has been appointed research psychologist at the Institute of Rehabilitation, New York University-Bellevue Medical Center. He will be a member of a psychiatric team studying the emotional aspects of rehabilitation under a \$73,500 grant from the Commonwealth Fund to New York University College of Medicine.

Venereal Disease Campaign.—The City of New York Department of Health, with the cooperation of the New York State Department of Health and the U. S. Public Health Service, will launch a month's campaign November 8 to bring under treatment an estimated 250,000 hidden cases of venereal diseases in the city. Representatives of the medical profession have assured the health department of their cooperation, and leaders in the fields of education, religion, health and welfare have been consulted in planning the campaign. Columbia University has prepared a series of fifteen radio transcriptions for broadcast during the campaign.

NORTH CAROLINA

Symposium on Therapy.—Duke University School of Medicine, Durham, will present a Symposium on Therapy November 4-6, at the school of medicine and Duke Hospital. Speakers include:

Harry Gold, New York, Newer Trends in the Management of Congestive Failure.
Carl V. Moore, St. Louis, Recent Advances in the Treatment of Anemia.
Harry L. Rogers, Philadelphia, Recent Therapeutic Trends in Allergic Diseases.
Cornelius P. Rhoads, New York, Recent Advances in the Treatment of Malignant Neoplastic Disease.
William L. Bradford, Rochester, N. Y., Recent Development in the Prevention and Treatment of Certain Communicable Diseases.
Wallace E. Herrell, Rochester, Minn., Present Status of Antibiotic Therapy.
Stewart H. Clifford, Boston, The Prevention of Neonatal Mortality.
Carl F. Schmidt, Philadelphia, Newer Trends and Methods in the Treatment of Peptic Agents.
Chicago, Therapeutic Advances in Endocrinology.
New York, Treatment of Rheumatism and Allied Disorders, Treatment of Syphilis.
Special Surgical Problems of Children.

On Friday at 8 o'clock a round table discussion and questions and answers program will be conducted with Dr. O. H. Perry Pepper, Philadelphia, as a moderator.

OHIO

Personals.—Dr. F. William Sunderman has been appointed head of the department of clinical pathology at the Cleveland Clinic Foundation. Dr. Sunderman received his M.D. and Ph.D. from the University of Pennsylvania, Philadelphia. During the war he was medical director of the Explosives Research Laboratory and an investigator and consultant for a division of the Office of Scientific Research and Development.—Dr. Shelby G. Gamble, assistant professor of physical medicine, Ohio State University College of Medicine, Columbus, has been appointed head of the department of physical medicine at the Cleveland Clinic, Cleveland. He has held similar position at the Starling-Loving University and Children's hospitals in Columbus.

Pediatric Psychiatry.—A new program of training in pediatric psychiatry is in progress at the University of Cincinnati College of Medicine, under the direction of Dr. Richard E. Wolf, assistant professor of pediatric psychiatry. The program is financed by the Commonwealth Fund and the Cincinnati Children's Hospital. Dr. Wolf serves in a consultant capacity for physicians at the Children's Hospital, working along with the physicians on their cases. He holds weekly conferences with hospital nurses and house staff and, in the fall, will lecture to students in the medical college. He is a graduate of Harvard University, Cambridge, Mass., and the University of Pennsylvania School of Medicine, Philadelphia. He has been on the university faculty since 1943.

OKLAHOMA

Spastic Paralysis Treatment Center.—Oklahoma's first center for the treatment of spastic paralysis was recently opened on the South Campus at the University of Oklahoma School of Medicine, Oklahoma City. The Norman Spastic Paralysis Institute is licensed for a maximum of 25 patients.

Postgraduate Study.—Hillcrest Memorial Hospital, Tulsa, will present its second Postgraduate Study Course, fall session, September 7 to December 30 for interns, residents and practicing physicians. There is no fee for the lectures, which are held every evening except Saturday and Sunday from 6 to 7 o'clock.

Personal.—Dr. Arthur A. Hellbaum, professor of physiology, University of Oklahoma School of Medicine, has been named associate dean of graduate studies and research. —Harold A. Shoemaker, Ph.D., has resigned as assistant dean, a position that he held since 1939, but will continue as professor of pharmacology. —Dr. Patric H. Mayginnies, Tulsa, has retired after fifty-one years' practice, forty of which have been in Tulsa. —The council of the Oklahoma State Medical Association has announced the appointment of Mr. John K. Hart as associate executive secretary of the association.

WASHINGTON

Seattle Mass Chest Survey.—Seattle is the fourth city in the nation and the first on the West Coast to inaugurate a mass chest roentgenogram survey. Surveys in Washington, Minneapolis and St. Paul have been completed. The program is sponsored by the Seattle-King County Health Department, the King County Anti-Tuberculosis League and the King County Medical Society. The state department of health, which is furnishing two mobile x-ray units, and the U. S. Public Health Service, which is furnishing sixteen mobile x-ray units, are cooperating with the sponsoring agencies.

Dr. Bennett to Head Anatomy Department.—Dr. H. Stanley Bennett, assistant professor of cytology, department of biology, Massachusetts Institute of Technology, Cambridge, has been appointed professor of anatomy and executive officer of the department of anatomy at the University of Washington School of Medicine, Seattle. Dr. Bennett obtained his M.D. degree from Harvard Medical School Boston, 1936. After an internship at Johns Hopkins Hospital, he was a fellow of the National Research Council and research fellow in anatomy. From 1939 to 1944 he was instructor in anatomy and pharmacology at Harvard Medical School, where he was made associate in anatomy in 1941. From 1942 until 1946 he served in the U. S. Navy.

WEST VIRGINIA

Health Conference Meeting Date Changed.—The annual meeting of the Northern District Health Conference, originally scheduled for October 8 at Fairmont, has been changed to October 22 to enable health workers to attend the psychiatric seminar at Huntington, October 6-7.

Cerebral Palsy Clinic.—A clinic for children with cerebral palsy was formally opened September 25 at Charleston under the sponsorship of the Kanawha County Society for Crippled Children and Adults. The clinic, which will be held in the Kanawha-Charleston Health Department clinic rooms, will be open from 9 to 4 every other Saturday, but it is expected that arrangements can be made soon to hold the clinic at least once each week. Treatment at the present time will be limited to 10 children, but every effort will be made to expand facilities so that additional patients may be accommodated. An orthopedist, a pediatrician, a physical therapist, an occupational therapist and a speech therapist will be in attendance at each session of the clinic, which will be in charge of the members of the medical advisory board. The West Virginia Department of Public Assistance, the Kanawha County Board of Education, the Parents Council (parents of cerebral palsied children), the American Business Club, Alpha Chi Omega, and other interested groups are working actively with the Crippled Children's Society in formulating plans for the clinic.

GENERAL

Meeting of International Cancer Research Commission Postponed.—The meeting of the International Cancer Research Commission, which was to have been held in Paris October 17-22, has been postponed until next year.

Medical Record Librarians Meeting.—The American Association of Medical Record Librarians will meet at the Elks Club, Los Angeles, October 18-22. Included in the program are three panel discussions: Standard Nomenclature on Monday evening, Statistical Data of Hospital Reports on Wednesday afternoon and a Medical-Legal Panel Friday morning. Sectional meetings will be held Friday afternoon.

Meeting of Clinical Pathologists.—The American Society of Clinical Pathologists will hold its annual meeting at the Drake Hotel, Chicago, October 12-15. The scientific program will open with a symposium on the cytologic diagnosis of cancer, followed by other scientific papers and the presentation of the Ward Burdick Award to Dr. Paul R. Cannon, Chicago. Scientific exhibits will be included. The annual banquet will take place October 13 at 7:30 p. m.

National Society Meeting.—The annual convention of the National Society for Crippled Children and Adults, Inc., will be held at the La Salle Hotel, Chicago, November 15-17. Outstanding speakers in the fields of medicine, health and education will discuss progress in work with the handicapped during the past year. The convention will be attended by physicians, therapists, educators, workers with the handicapped and representatives of the society's more than 2,000 state and local units throughout the United States, Canada, Alaska and Hawaii.

Millions for Cancer Research.—The American Cancer Society has awarded \$3,500,000 for cancer research in the year beginning September 1. Specific allotments include Columbia University, \$242,288 in fellowships and individual and institutional grants; Memorial Hospital and the Sloan-Kettering Institute, \$136,276, and Cornell University, \$76,205. The largest allotment was made to the University of Chicago, which will receive \$332,047. Institutions and individual scientists in thirty states participate in the awards, with groups in New York state receiving about one sixth of the total. Massachusetts, Illinois and Pennsylvania follow in that order.

Meeting of the Society for Study of Arteriosclerosis.—The American Society for the Study of Arteriosclerosis will hold its annual meeting at the Hotel Knickerbocker, Chicago, October 31 to November 1 under the presidency of Dr. William B. Kountz, St. Louis, Mo. Papers to be presented include the following:

- I. Mark Scheinker, Cincinnati, Cerebral Vascular Changes in Arterial Hypertension
- o. Some Aspects of the Intermediary
- Minn., Clinical Diagnosis of Arterio
- sclerosis.
- Russell L. Holman, New Orleans, Studies on the Relationship of Diet and Renal Insufficiency to Arterial Disease.
- Rudolf Altschul, Saskatoon, Canada, New Experiments in Arterio-sclerosis.

The guest speaker at the banquet October 31 at 7:30 p. m. will be Dr. Cassius J. Van Slyke, Washington, D. C., director, National Heart Institute.

Marriages

WILLIAM CARL LUDWIG DIEFENBACH III, Long Island, N. Y., to Miss Martha Kahle of Shelter Island, September 11.

HOWARD CARTER DAVIS JR., Greenwich, Conn., to Miss Patricia Nichols French of New York, July 20.

CHARLES R. WILLSON, Wilmington, Ill., to Mrs. Sallie Satterfield of Nokomis at Taylorville, July 2.

RICHARD E. H. DUISBERG, Philadelphia, to Miss Agnes Adamy of New Brunswick, N. J., July 16.

DAVID L. ROSENCRANS, Towanda, Pa., to Miss Barbara S. Allen in Montclair, N. J., July 17.

MARLIN BOYD HOGE to Miss Martha Nell Greenwood, both of Little Rock, Ark., August 16.

CHARLES M. ALLABEN, Binghamton, N. Y., to Mrs. Mary K. Stevens in Buffalo, July 1.

WILLIAM R. DEWAR to Miss Thelma J. Neidig, both of Allentown, Pa., July 10.

HELMUT BAUM, Berlin, Germany, to Miss Betty Marsh of St. Paul, August 22.

PHILIP H. BAKER to Miss Judith Elster, both of Los Angeles, July 11.

Deaths

Solomon Solis-Cohen, Melrose Park, Pa., died in the Jewish Hospital, Philadelphia, July 12, aged 90, of bronchopneumonia and parkinsonism. Dr. Solis-Cohen was born in Philadelphia Sept. 1, 1887 and received his medical degree from Jefferson Medical College, Philadelphia, in 1883. Five years later he was appointed lecturer in clinical medicine. He was professor of clinical medicine from 1902 to 1927, when he was made emeritus professor. Dr. Solis-Cohen had been professor of clinical medicine and therapeutics at the Philadelphia Polyclinic and the College for Graduates in Medicine from 1887 to 1902 and lecturer in therapeutics at Dartmouth College from 1890 to 1892. In 1902 and 1903 he was chairman of the Section on Materia Medica, Pharmacology and Therapeutics of the American Medical Association and in 1907 a member of the House of Delegates. He was a fellow of the College of Physicians of Philadelphia, American College of Physicians and the American Association for the Advancement of Science and an honorary member of the Medical and Chirurgial Faculty of Maryland and other medical societies. From 1899 to 1913 he was a recorder for the Association of American Physicians, and in 1898 and 1899 was president of the Philadelphia County Medical Society. Dr. Solis-Cohen served on the Philadelphia Board of Education from 1925 to 1944 and on the council of the Jewish Agency for Palestine from 1920 to 1942, and he was a founder of the Jewish Theological Seminary of America. From 1887 to 1927 he was physician at Philadelphia General, Jefferson and Jewish hospitals and later was consulting physician. He was a trustee of the United States Pharmacopoeia from 1920 to 1940, and was the author of "Therapeutics of Tuberculosis," 1891, "Essentials of Diagnosis" with A. A. Eshner, 1892-1900, and "Pharmacotherapeutics, Materia Medica and Drug Action" with T. S. Githens, 1928, and editor and contributing author of "A System of Physiological Therapeutics" in eleven volumes, from 1901 to 1904. In 1899 he was a delegate to the third Zionist Congress in Basle.

Berthold Steinbach Pollak ♂ Jersey City, N. J.; born in Vienna, June 26, 1873; Dartmouth Medical School, Hanover, N. H., 1896; member of the House of Delegates of the American Medical Association in 1928 and from 1931 to 1933; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served as vice president and president of the Hudson County Medical Society; member and director of the National Tuberculosis Association, which he represented at various times as delegate at conferences of the International Union Against Tuberculosis at London, Paris, Lausanne, Brussels, Oslo, Warsaw and Washington; named U. S. delegate to a tuberculosis conference held in Rome; member and director of the American Heart Association and the American Trudeau Society; past president of the New Jersey Public Health and Sanitary Association, New Jersey Tuberculosis League and the New Jersey Hospital Association; member of the executive committee of the Hudson County Tuberculosis League; chairman of the medical board of the Deborah Jewish Consumptive Sanatorium in Browns Mills; phthisiologist at St. Mary's Hospital, Hoboken, Beth Israel Hospital, Newark, Jersey City Medical Center and Christ Hospital; early in his career appointed medical director of the Hudson County Tuberculosis Hospital, which in 1946 was renamed in his honor the Berthold Steinbach Pollak Hospital for Chest Diseases; died in his apartment at the hospital June 27, aged 75, of cerebral thrombosis.

Otto Marburg, New York; born in Roemerstadt, Austria, May 25, 1874; Medizinische Fakultät der Universität, Wien, Austria, 1899; clinical professor of neurology at the Columbia University College of Physicians and Surgeons; member of the American Medical Association and the New York Academy of Medicine; honorary member of the American Neurological Association, the Philadelphia and New York Neurological societies, the Vienna Medical Society and various other scientific associations; served as a vice president of the International Neurological Congress; specialist certified by the American Board of Psychiatry and Neurology; for many years chief of the Neurological Institute of the University of Vienna; on the consulting staffs of Montefiore Hospital and the New York Post Graduate Medical School and Hospital; author of "Microscopic Topographic Atlas of the Central Nervous System," the third edition published in 1927, and many other books on his speciality; died in the Mount Sinai Hospital June 13, aged 74.

Otto August Fiedler ♂ Sheboygan, Wis.; born in Stockbridge, Wis., March 9, 1873; Wisconsin College of Physicians and Surgeons, Milwaukee, 1902; past president of the state

board of health, State Medical Society of Wisconsin and the Sheboygan County Medical Society; served in the Spanish-American War and with the American Expeditionary Forces in France during World War I; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; formerly assistant professor of surgery at the Marquette University School of Medicine, Milwaukee; past president and formerly chief of staff of the Sheboygan Clinic, of which he had been one of the organizers in 1921; instrumental in the organization of the Sheboygan Memorial Hospital, where he had been chief of staff and where he died June 22, aged 75, of coronary thrombosis and carcinoma of the bladder.

David von den Berg Le Mone ♂ Columbia, Mo.; born in Grand Rapids, Mich., July 21, 1904; Washington University School of Medicine, St. Louis, 1934; associate professor of roentgenology at the University of Missouri School of Medicine; specialist certified by the American Board of Radiology, Inc.; member of the Radiological Society of North America, Inc., and the American College of Radiology; chief of staff of Boone County Hospital; roentgenologist at Audrain Hospital, Mexico, St. Joseph's Hospital in Boonville and St. Mary's Hospital in Jefferson City; roentgenologist at the University Hospitals and the Ellis Fischel State Cancer Hospital; consulting roentgenologist at the State Hospital in Fulton and the Missouri State Penitentiary Hospital in Jefferson City; died in Glickner Hospital, Colorado Springs, June 11, aged 43 of coronary thrombosis.

Thomas Trovillo Sheppard ♂ Pittsburgh; born in Pittsburgh, Sept. 17, 1891; Columbia University College of Physicians and Surgeons, New York, 1918; associate professor of medicine at the University of Pittsburgh School of Medicine; president of the Allegheny County Medical Society; past president of the Pittsburgh Academy of Medicine; on the staffs of the Magee, Presbyterian and Eye, Ear, Nose and Throat hospitals; director of the Renziehausen Memorial Ward and Clinic at Children's Hospital; member and chief of staff at Western Pennsylvania Hospital, where he died July 5, aged 56, of encephalomalacia and arteriosclerosis.

Harry Anthony Keenan, Stoughton, Wis.; Rush Medical College, Chicago, 1903; served during World War I; lieutenant colonel, medical reserve corps, not on active duty; past president of the board of trustees of the Lake View Sanatorium in Madison; on the visiting staffs of the Methodist Hospital in Madison and Stoughton Community Hospital; member of the American Medical Association; in 1943 was selected by *Look* magazine as the typical home front physician in wartime; died in the Wisconsin General Hospital, Madison, July 1, aged 70, of cerebral thrombosis and diabetes mellitus.

James Edwards Poore ♂ Lieutenant Colonel, U. S. Army, retired, Washington, D. C.; born on Feb. 24, 1876; Bellevue Hospital Medical College, New York, 1897; veteran of the Spanish-American War; served on the Mexican border in 1916 and overseas during World War I; served with the Army of Occupation in Germany; postwar duties included service in China and the Philippines; entered the medical corps of the U. S. Army as a major in 1920; promoted to lieutenant colonel in 1937; retired Feb. 29, 1940; died in the Walter Reed General Hospital April 3, aged 72.

John Wesley Judd ♂ Ithaca, N. Y.; born in 1870; University of Vermont College of Medicine, Burlington, 1896; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; fellow of the American College of Surgeons; past president of the Tompkins County Medical Society; served as health officer and coroner; affiliated with Tioga County General Hospital in Waverly and on the staff of Tompkins County Memorial Hospital, where he was president of the staff and where he died June 6, aged 78, of heart disease.

Sarkis H. Abkarian, Pelham, N. Y.; University of the City of New York Medical Department, New York, 1889; died in the New Rochelle (N. Y.) Hospital June 24, aged 85, of cerebral thrombosis and arteriosclerosis.

Frank Benjamin Allison, Detroit; Detroit College of Medicine, 1905; member of the American Medical Association; affiliated with St. Luke's Hospital; died in the Harper Hospital June 30, aged 68, of coronary thrombosis.

Harry William Vernet Beals ♂ Mayview, Pa.; Temple University School of Medicine, Philadelphia, 1937; interned at the Hamot Hospital in Erie; member of the American Medical Association; served in the medical corps, Army of the United States, during World War II; associated with the Mayview Hospital; died June 26, aged 37, of coronary occlusion.

Richard Lorenzo Brown, Gloster, Miss.; Cincinnati College of Medicine and Surgery, 1889; member of the American Medical Association; died in McComb, June 18, aged 81.

William J. Burns, Glen Cove, N. Y.; Bellevue Hospital Medical College, New York, 1882; at one time health officer of the town of Oyster Bay; died in May, aged 89.

Edward Buehler Clement * Salisbury, N. C.; Jefferson Medical College of Philadelphia, 1906; served during World War I; died in Brunswick, Ga., June 18, aged 66, of coronary occlusion.

William Henry Chambers, Dierks, Ark. (licensed in Arkansas in 1903); died in Little Rock June 4, aged 69.

Corben Jay Decker * Surgeon, Lieutenant Commander, U. S. Navy, retired, Athens, Ga.; Jefferson Medical College of Philadelphia, 1880; entered the U. S. Navy in July 1906 and retired Aug. 31, 1907 for disability resulting from an incident of service; served during World War I; died in the General Hospital June 21, aged 86, of coronary thrombosis.

Walter den Bleyker * Kalamazoo, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1900; city physician in Kalamazoo from 1906 to 1908; past president of the Kalamazoo Academy of Medicine; at one time superintendent of Fairmount Hospital; died June 29, aged 71, of heart failure.

Frederick Luke Doucett, Weymouth, Mass.; Tufts College Medical School, Boston, 1900; member of the American Medical Association; for many years a member and formerly chairman of the board of health; died June 19, aged 78, of arteriosclerotic heart disease and cerebral hemorrhage.

Harry Baker Dow, West Springfield, Mass.; Baltimore Medical College, 1911; also a pharmacist; member of the board of health; died in the Springfield (Mass.) Hospital June 7, aged 71, of hypertensive cardiovascular disease and hemiplegia.

Stanley Waldo Dowling * Santa Cruz, Calif.; Cooper Medical College, San Francisco, 1912; died in the French Hospital June 26, aged 60, of carcinoma of the colon and coronary thrombosis.

Henry Cuttino Dozier, Ocala, Fla.; University of Pennsylvania Department of Medicine, Philadelphia, 1903; member of the American Medical Association and the Southeastern Surgical Congress; fellow of the American College of Surgeons; past president of the Florida Medical Association; on the staff of Monroe Memorial Hospital; died in Lavallette, June 16, aged 69, of coronary occlusion.

Henry A. Dunphy * Palmer, Mass.; Baltimore Medical College, 1908; associate medical examiner for the Palmer district of Hampden County; served on the staff of Mercy Hospital in Springfield, where he died June 11, aged 66, of cerebral embolism.

Willis E. Elder, Columbus, Ohio; College of Physicians and Surgeons, Baltimore, 1895; formerly assistant chief medical examiner of the Ohio State Industrial Commission; died June 14, aged 81, of chronic myocarditis.

Carrie Innes Felch, Boston; Tufts College Medical School, Boston, 1906; member of the American Medical Association; died June 11, aged 75, of cerebral hemorrhage.

Elisha Flagg, Boston; Harvard Medical School, Boston, 1901; member of the American Medical Association; at one time treasurer of the Boston Medical Library; served on the staff of Massachusetts General Hospital; died June 8, aged 82, of heart disease.

W. Sturgis Frankenburger * Carmichael, Pa.; Jefferson Medical College of Philadelphia, 1911; served during World War I; formerly member of the school board; died June 1, aged 61, of coronary occlusion, arteriosclerosis and diabetes mellitus.

Henry Gray Glover, Jackson, Mich.; the Hahnemann Medical College and Hospital, Chicago, 1882; member of the American Medical Association; died June 21, aged 87, of coronary thrombosis.

James Mines Godfrey, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1904; Jefferson Medical College of Philadelphia, 1906; professor emeritus of anesthesia at the Hahnemann Medical College and Hospital of Philadelphia; member of the American Society of Anesthesiologists; died at Buck Hill Falls, Pa., June 30, aged 67, of carcinoma of the left lung.

Charles Augustus Goodrich * Hartford, Conn.; Columbia University College of Physicians and Surgeons, New York, 1896; member of the New England Pediatric Society; past president of the Hartford County Medical Society; affiliated with Hartford Hospital, where he died June 13, aged 76.

Herschel Willman Goss, Indianapolis; Indiana University School of Medicine, Indianapolis, 1929; member of the American Medical Association; died May 21, aged 44, of cerebral hemorrhage and malignant hypertension.

William Brandon Gregory * Owego, N. Y.; Syracuse University College of Medicine, 1934; interned at the Binghamton City (N.Y.) Hospital; died in Lima, Ohio, June 12, aged 41, of injuries received in a plane crash.

Bert C. Hall, Pompeii, Mich.; Detroit College of Medicine, 1897; fellow of the American College of Surgeons; for many years associated with the R. B. Smith Memorial Hospital in Alma; died June 30, aged 80, of coronary embolus.

F. L. C. Helm * Baltimore; Georgia College of Eclectic Medicine and Surgery, 1912; formerly coroner of the Western District; on the staff of the Church Home and Hospital; died in Bon Secours Hospital June 7, aged 64, of thyrotoxicosis.

William Francis Hill, Jersey City, N. J.; Columbia University College of Physicians and Surgeons, New York, 1919; died in the Jersey City Medical Center June 20, aged 52.

Wilgus Alexander Holman, London, Ohio; Jefferson Medical College of Philadelphia, 1923; member of the American Medical Association; died June 10, aged 50, of coronary occlusion.

Vincent Joshua Horton * Calmar, Iowa; State University of Iowa College of Medicine, Iowa City, 1923; died in the Kahler Hospital, Rochester, Minn., May 31, aged 51, of embolism following an operation.

Edward Lamar Kelly, Repton, Ala.; Medical College of Alabama, Mobile, 1900; for many years county health officer; member of the American Medical Association; died June 5, aged 77, of cerebral hemorrhage.

John Timothy Kennedy * Medical Inspector, Commander, U. S. Navy, retired, Ogunquit, Me.; University of the City of New York Medical Department, New York, 1894; fellow of the American College of Surgeons; entered the U. S. Navy in 1900 and retired June 30, 1936; died in Naval Hospital, Portsmouth, June 3, aged 75, of coronary thrombosis.

Perry Firestone King * Alliance, Ohio; Western Reserve University Medical Department, Cleveland, 1904; fellow of the American College of Surgeons; affiliated with Alliance City Hospital; for many years closely identified with Mount Union College; died May 16, aged 70, of coronary occlusion.

Edgar Thorp Lassetter, Albuquerque, N. M.; Southern College of Medicine and Surgery, Atlanta, 1913; also a graduate in pharmacy; veteran of the Spanish-American War; a member of the state board of health and the board of trustees of the Lovelace Foundation for Medical Education and Research; vice president of the board of governors of the Lovelace Clinic; on the staff of St. Joseph Hospital; died June 27, aged 73, of cerebral hemorrhage.

Carl Copeland MacCorison * North Berwick, Me.; Dartmouth Medical School, Hanover, N. H., 1906; for many years superintendent of the North Reading (Mass.) State Hospital; died in the Henrietta D. Goodall Hospital, Sanford, June 3, aged 70.

John Harry Mallery, Trail, Ore.; Medical Department of the University of California, San Francisco, 1902; served during World War I; formerly affiliated with the U. S. Public Health Service reserve and on the staffs of various Veterans Administration hospitals; died June 30, aged 70, of heart disease.

Earle Clarence McBride * Terre Haute, Ind.; University of Louisville Medical Department, 1907; served as president of the Terre Haute Academy of Medicine and the city board of health; chief of medical service of St. Anthony's Hospital; died June 5, aged 73, of coronary occlusion.

Vincent Valens McCabe, Millbrook, N. Y.; Baltimore Medical College, 1901; died May 30, aged 73, of subdiaphragmatic abscess and toxemia.

Leo Thomas McCready, Boston; Tufts College Medical School, Boston, 1906; member of the American Medical Association; examining physician for the local Selective Service Board during World War II; died May 5, aged 68, of carcinoma of the larynx.

Edel Farnandis McIntosh Sr., Chattanooga, Tenn.; Meharry Medical College, Nashville, 1912; formerly city physician; died May 8, aged 60, of coronary occlusion.

John Franklin Mecluskey * Philadelphia; Maryland Medical College, Baltimore, 1911; on the staffs of the Episcopal and St. Mary's hospitals; died in the State Hospital, Marlboro, N. J., June 9, aged 71, of cerebral hemorrhage.

Henry Chalmers Mitchell, New Castle, Pa.; Jefferson Medical College of Philadelphia, 1903; member of the American Medical Association; medical examiner for the public schools; on the staff of the Jameson Memorial Hospital, where he died June 6, aged 69, of carcinoma of the liver.

Edward Everett Moore, Mount Airy, N. C.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1891; died in Morganton May 26, aged 89.

John Aloysius Murphy, New Haven, Conn.; New York University Medical College, New York, 1897; on the staff of the Hospital of St. Raphael, where he died June 1, aged 76, of carcinoma of the transverse colon.

James Cheston Ogden, Long Beach, Calif.; State University of Iowa College of Medicine, Iowa City, 1930; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology; on the staffs of Seaside Memorial, St. Mary's and Community hospitals; died May 25, aged 45.

Thomas L. Peacock, Lake Odessa, Mich.; Michigan College of Medicine and Surgery, Detroit, 1899; died May 27, aged 79, of valvular heart disease.

Clarence Fay Rinkle, New Hartford, N. Y.; Albany (N. Y.) Medical College, 1916; died May 30, aged 60, of pulmonary tuberculosis.

Gus Thompson Rumbaugh, Villisca, Iowa; Kentucky School of Medicine, Louisville, 1890; died in Clarinda May 1, aged 81, following a fracture of the right hip due to a fall.

George Walter Sapp, Newark, Ohio; Ohio State University College of Medicine, Columbus, 1911; member of the American Medical Association; died May 23, aged 61, of coronary occlusion.

Henry Snure, Los Angeles; University of Louisville School of Medicine, 1910; specialist certified by the American Board of Radiology, Inc.; fellow of the American College of Physicians; member of the American Roentgen Ray Society, Radiological Society of North America and the American College of Radiology; served during World War I; for many years on the staff of California Hospital; died in St. Vincent's Hospital May 17, aged 60, of cerebral hemorrhage.

George Elmer Strout, Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1901; formerly assistant professor of ophthalmology and otolaryngology at his alma mater; chief of staff, Wells Memorial Dispensary; member of the staffs of University, Eitel, Northwestern and St. Barnabas hospitals; oculist to the Minneapolis and St. Louis Railroad; died May 10, aged 75, of coronary thrombosis and myocardial infarction.

Martillus L. Todd, Major, U. S. Army, retired, Charleston, S. C.; Baltimore Medical College, 1897; at one time on the faculty of his alma mater; entered the medical corps of the U. S. Army as a major in 1920 and retired Jan. 31, 1931 for disability in line of duty; served during World War I; died in the Roper Hospital, May 30, aged 78, of carcinoma of the prostate.

LIEUT. HILERD W. JENKINS
(MC) U.S.N.R., 1914-1942

COMDR. MEINOLPH V. KAPPIUS
(MC) U.S.N.R., 1899-1946

CAPT. ALEXANDER A. ST. CLAIR,
M.C., A.U.S., 1911-1945

KILLED IN ACTION

Hilerd Westley Jenkins, River Forest, Ill.; aged 28; born in Forest Park March 6, 1914; University of Illinois College of Medicine, Chicago, 1938; interned at the Cook County Hospital in Chicago; member of the American Medical Association; entered active duty as a lieutenant in the medical corps of the U. S. Naval Reserve in December 1941 at the Naval Hospital in San Diego; on Dec. 9, 1941 assigned to the *Harris*, a hospital ship which during the ensuing months made numerous trips to Pearl Harbor; on Feb. 22, 1942 transferred to the destroyer U. S. S. *Warden* of the Pacific Fleet and in September 1942 to the U. S. S. *Moussen*, which on Nov. 13, 1942 engaged in battle with the enemy off Savo Island near Guadalcanal with great loss of life.

Meinolph Valen Kappius, Long Beach, Calif.; born in West Point, Neb. Feb. 23, 1899; Harvard Medical School, Boston, 1924; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; member of the American Medical Association and the Massachu-

setts Medical Society; formerly assistant in obstetrics at his alma mater and affiliated with Boston Lying-In and the Massachusetts General hospitals in Boston and the Free Hospital for Women; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve in April 1942; promoted to commander; officially reported missing in action Jan. 24, 1945, while attached to the U. S. S. *Kadasak Bay*; the plane in which he was flying was lost in the vicinity of the Admiralty Islands; the date of death was determined for administrative purposes within the Naval service to be Jan. 25, 1946, aged 47.

Correction.—Above is the correct photograph of Capt. Alexander A. St. Clair, M.C., A. U. S., who was reported missing in action on a flight over the Asiatic area July 13, 1943, and declared dead as of Dec. 19, 1945. In a number of copies of THE JOURNAL, September 18, page 227, Dr. St. Clair's obituary was printed under the picture of Comdr. Meinolph V. Kappius, M.C., U.S.N.R., whose obituary appears on this page.

Aug. 28, 1948.

Record Vital Statistics

During the war, with all its hardships and privations, British vital statistics actually showed an improvement. Now, when we are still suffering from the after-effects of the war in the form of scarcity and rationing of food, the same improvement continues. New low records for infant mortality, the general death rate and deaths from influenza in the first quarter of the present year are shown in the Registrar-General's returns, which have just been published. The provisional infant mortality rate was 41 per thousand live births, the lowest ever recorded for any first quarter. It was 11 below the figure for the same period last year and 25 below the average for the March quarters of the preceding ten years. It has already been announced that the provisional rate for the second quarter of this year is 31, the lowest on record for any quarter.

Births during the same period showed a rate of 18.9 per thousand compared with 17.8 for the preceding quarter and 22.8 for the corresponding quarter of 1947. The average birth rate for the first quarters of the five years 1942 to 1946 was 16.7. The death rate for the March quarter of 1948 was 12.4 per thousand, a new low record for that quarter. It compares with 17.1 for the corresponding quarter of 1947 and an average for the first quarters of 1942 to 1946 of 14.3. Deaths from influenza among civilians numbered only 644. The lowest number previously recorded in a first quarter was 1,470 in 1945, and the ten year average for first quarters of 1938 to 1947 was 3,800.

Two Healthy Young Cadets Die After an Eight Mile Training March

The country has been shocked by the deaths of two officer cadets, aged 19, during normal military training. They collapsed after an 8 mile route march partly over country and partly along roads, which had been arranged as part of their normal training. Each was in his thirteenth week of training. There was no specified time in which the march had to be completed. The syllabus, which had been carried out, included a 4 mile march without equipment but with rifles and a 2 mile march in battle order. Of the 32 members of the squad 3 were subsequently admitted to hospital, and of these the 2 mentioned died. At the coroner's inquest it was stated that the necropsies showed no signs of disease; the cadets were quite healthy. The only other factor was an exceedingly hot day. The verdict was death from heat stroke. No blame was attached to any one in command. But the War Office issued an order that exercises should be less stringent during the hot weather.

Shortage of Doctors and Excess of Applicants for Entry to Medical Schools

The National Health Service, which in one blow establishes medical socialism for the whole country, has come into force with remarkably little disturbance. Its efficacy, of course, depends on the quantity and quality of the doctors operating it. The former is certainly deficient. According to some only half the requisite number are available. There is no lack of entrants for the medical schools. The trouble is that the schools cannot immediately expand because laboratory and lecture room space is limited, as is the number of teachers. For each vacancy in the schools the applicants for entry range from 3 to 20, though this ratio exaggerates the excess because to an unknown extent some candidates apply to several schools. The difficult task of selection is carried out by the dean alone in half of the schools; at others by a committee. In an article devoted to

student selection, *Lancet* declares that this has become harder than ever. For the coming year one London school has 700 applicants for 65 places, another 600 for 100 and a third 400 for 20 places. The question, "Is there any good reason for rejection?" has given way to "Is there any good reason for acceptance?" Methods vary widely. The universities require candidates to complete forms of questionnaires and a confidential report is then obtained from a head master or employer. Primary selection is made and then final selection by interview. The universities are so filled with students of this country that candidates from overseas, whether from the Dominions or Colonies or from foreign countries, can seldom be accepted.

An Operating Theater for the Training of Students

The Nuffield Operating Theater, specially designed for the training of students and for experiments in new surgical methods, was opened at Johannesburg by Sir Hugh Cairns, professor of surgery at Oxford University, who is on lecture tour in South Africa. It seems to be the only one of the kind in existence. It was designed by W. E. Underwood, professor of surgery in the University of Witwatersrand. It will enable students to learn theater technic at their leisure, instead of in hospitals, where precision and speed are essential. It is a replica of the most modern hospital theaters.

ITALY

(From Our Regular Correspondent)

FLORENCE, Aug. 7, 1948.

Intoxication With Trinitrotoluene

At a meeting of the Association for Legal and Occupational Medicine presided over by Professor Palmieri, Drs. Caccuri and Sessa discussed intoxication by trinitrotoluene. They reported the results of research on 100 workmen who unloaded munitions in a dockyard near Naples. The workers were exposed to contact with trinitrotoluene either through the air because of the vapors, by the cutaneous route, or by the gastric route in the form of powder. The workmen had been exposed to trinitrotoluene for periods varying from three to ten months.

The symptoms reported were disturbances of the liver (pain, hepatomegaly, subicterus, or icterus); nervous disorders (headaches, vertigo, asthenia); disturbances of digestive apparatus (gastralgia, abdominal pains, anorexia, nausea, vomiting). Second in order were disturbances of the respiratory apparatus and of the cardiovascular apparatus (bradycardia, arterial hypotension).

Laboratory studies showed a positive Takata-Ara reaction and a positive Webster urine reaction in some of the cases, and an increase in azotemia in some cases. The examination of peripheral blood revealed a reduction of hemoglobin and a decrease of red blood corpuscles in nearly all persons studied, mild anisocytosis, then chylocytosis in many cases; normal or subnormal white blood cell counts; reduction of blood platelets in the great majority of the workmen and a definite increase in reticulocytes in 50 per cent of the persons studied. In nearly all persons there was a drop of the neutrophils containing pathologic granulations in the granulograms which were made according to the indications of Benda: the percentual number of intermediate form was predominant as compared to all the others; next in order were the normal forms, and last those of the extreme type. The pathologic neutrogranulogram may be considered as in close connection with the toxic injury to the peripheral blood and to the liver. The constancy of the observation makes it useful for early diagnosis of intoxication with trinitrotoluene and as an index of the degree to which the blood and the liver are affected.

At this meeting an order of the day was approved by which the Association of Legal and Occupational Medicine was held

to vote that occupational medicine should be included as an obligatory branch of study in the last biennium at the medical faculty. At the great universities, schools for specialists of occupational medicine should be instituted and hygiene should become an obligatory branch of study at the industrial and technical intermediate schools.

Discussion on Immunology

At the Congress of the Salerno Medical and Surgical Association, Professors Califano and Merlino presented reports on the subject "Blood in the Light of New Knowledge." Professor Califano discussed the development of the concepts of immunology, emphasizing the nature of antibodies. Concerning gamma globulin he stated that one may think of it as a protein, the origin and significance of which have to do exclusively with immunity, and that since antibodies are constituted by gamma globulin or by components closely related to it, the problem identifies itself with that of the formation of serum globulin. There may be no doubt about the significance of lymphatic tissue in serologic immunity, although one must recognize always the important part of the reticulohistiocyte system in the genesis of the humoral immunity. The concept of elaboration of antibodies in strict dependence on protein alimentation may be considered as firmly grounded. The only alimentary factor which has an effect on the contents of antibodies in the serum is the amount of aminoacids in the diet.

In discussing the problem of blood transfusions, Professor Merlino pointed out the modern views on agglutinogens and agglutinins, on the Rh factor, and on the Hr factor.

The New Commissioner for Public Health

Professor Cotellessa, member of Parliament, has been nominated High Commissioner for Hygiene and Public Health. He started his scientific career at the hospital for infectious diseases "D. Cotugno" in Naples, then devoted himself to pediatry and as an assistant at the clinic of Naples and other Italian medical centers, becoming an associate professor in this speciality. He founded the Abruzzo section of the Pediatric Association and organized a service of consultation and assistance for the National Maternity and Child Welfare in the Province of Chieti.

BUENOS AIRES

Aug. 15, 1948.

Thoracic Esophagectomy and Neoplasm of the Esophagus

In the National Academy of Medicine of Buenos Aires Prof. Dr. Ricardo Finochietto, together with Dr. J. Horacio Resano, related the results in 100 patients who survived this operation. Since the first transthoracic esophagectomy done by him thirty years ago the good results have been obtained with better anesthesia, a better understanding of the physiology of operative shock and a better knowledge of surgical pneumothorax. Essential are the unlimited operative transfusion (according to the necessities of the patient), avoiding anoxia, and also standardization of the operation, trained personnel, appropriate instruments and antibiotics.

Of the 100 patients with cancer 50 were operable, but only 25 were resectable. For resection the authors fix an arbitrary limit: 7 cm. in the roentgenologic picture; in cases of greater tumors the resection is laborious or absolutely impossible. Neither the age nor bad general conditions are considered as absolute contraindications. The actual mortality is 40 per cent.

The authors are of the opinion that the Thorek method leaves the patient practically invalid with few chances for normal deglutition; furthermore, 32 of the 33 patients who survived protested and wanted the artificial esophagus, only 1 being satisfied with the two fistulas. Seven of these 33 patients are

alive. The maximum time of survival after esophagoplasty is two years.

The other terminal method, anastomosis, permits an immediate restoration of the deglutitive function; 22 of 67 patients treated by this method died of recurrences; the longest time a patient survived was four years and seven months. Of the 67 patients 47 were operated on according to the method of Biondi; 9 that of Garlock, and 11 that of Lewis.

The authors consider that the prolongation of life is greatest with resection of the tumor with transthoracic anastomosis.

Thyroid Insufficiency Due to Inhalation of Sulfonamide Drugs

Prof. Dr. E. B. del Castillo and his collaborators, Dr. F. Irigoyen and F. Vivone, observed 2 cases of thyroid insufficiency after prolonged inhalation of "prontosil" (an azosulfamide) due to working circumstances; only one of the patients had goiter. Both improved with thyroid medication. Such cases can be considered as professional accidents. It seems convenient that specialists of the respiratory tract control the thyroid function during prolonged treatment with sulfonamide nebulization.

Excretion of Pituitary Gonadotropins During Amenorrhea

In order to make a classification on a physiologic basis Drs. A. de la Balze and J. Argonz employed the test of pituitary gonadotropin in the urine (modification of the biologic method of Zondek) in 83 amenorrheic women. According to 155 tests of the follicle-stimulating hormone which had been carried out, these patients could be divided in three principal groups, according to the amount of this hormone (increased, diminished or normal). This method is considered useful and permits one to state in a case of amenorrhea the different types of gonadal insufficiency, the stage of the gonadotropic pituitary function and as result of these items, the physiopathologic diagnosis of the amenorrheas.

Pan-American Congress of Gastroenterology

The subjects for discussion, at this congress were mentioned in *THE JOURNAL*, June 12, page 659. The American guests, Drs. H. Bockus, C. A. Broders and B. B. Crohn, lectured also in the National Academy of Medicine, which designated them honorary members. Their contributions to the congress have been much esteemed. Other prominent lecturers came from Brazil, Chile, France, Mexico, Spain and Uruguay. The deliberations on the main subject, "Chronic Cholecystitis without Stones," took place under the chairmanship of Prof. Dr. Carlos Bonorino Udaondo, President of the National Academy of Medicine. The Interamerican Association of Gastroenterology has been founded, with headquarters in Buenos Aires. The second congress will be held in 1950 in Rio de Janeiro, with the main subject "Pathology of the Small Intestine."

Brief Items

The Argentine Society of Microbiology has been founded, with Prof. Dr. A. Bachman as president.—Dr. J. Taiana has been designated titular professor of thoracic surgery, as successor of Prof. José Arce.—A commission of experts has been created for studying the administration of streptomycin, under the chairmanship of Prof. Dr. Roque A. Izzo, Interventor of the Faculty of Medicine of Buenos Aires.—The Argentine League against Epilepsy has been founded, as a branch of the International League against Epilepsy; president is Dr. Aquiles Garciso, whose address is Argentine Medical Association, calle Santa Fe 1171, Buenos Aires.—The *Revista de Sanidad Aeronáutica* is a new trimonthly periodical, edited by the Dirección General de Sanidad de la Secretaría de Aeronáutica.

Correspondence

FURTHER NOTES ON MEDICAL EDUCATION IN GERMANY

To the Editor:—In the May 1, 1948 issue of THE JOURNAL, page 5, Dr. Irving S. Wright reported on the present status of medical education in Germany and Austria. It might be of general interest to supplement Dr. Wright's discussion with information concerning German efforts to improve the reported shortcomings. Originating with a request from German sources (particularly from the frequently mentioned Dr. F. Volhard), it was my mission to serve as a consultant of our military government to assist in the rehabilitation and reform of German medical schools. The German origin of the request was an

FACULTIES

Appointment of part time clinical teachers, which has been more or less unknown in Germany in the past, is looked on with definite interest. The unfinished denazification procedures are a great obstacle in initiating such appointments as well as in sufficient staffing of the faculties in general. The denazification laws allow certain groups of persons to practice medicine, but do not allow them to teach. Other groups are permitted to do research, but again not to teach. Denazification laws are handled differently by the different occupation powers. German medical educators who are acceptable to one power are not acceptable to another. However, it is hoped that the denazification procedures will be finished this year. For security reasons, medical research projects must be submitted to the powers of occupation.

invaluable help in overcoming the primary defense reaction toward suggestions proposed by one associated with medical education of an occupying power.

The main achievement of this mission was the establishment of an organization called Ausschuss für die Ausbildung und Fortbildung von Aerzten, an organization with aims similar to those of our Council on Medical Education and Hospitals. The present chairman of the Ausschuss is Prof. Kurt Felix, head of the Department of Vegetative Physiology at the University of Frankfurt am Main. This Ausschuss will meet every year on Ascension Day; its meetings are public, and participation is open to all members of the medical profession, including medical students. To everyone familiar with German medical education, the establishment of such an Ausschuss is a step forward that will make medical education in that country less autocratic and in general, of course, a step forward in making medical education in Germany a continuous problem, as it already is in this country. Founded only a year ago, the Ausschuss is still in its infancy.

STUDENT BODY

It is assumed that the overcrowding of German medical schools will be over by the end of this year. Paradoxical as it may seem, it will not be possible to limit the number of students and to introduce student quotas on the basis of available facilities before the present overcrowding has passed. The reason for this delay is that the overwhelming majority of the present medical students are veterans, and it can be readily understood that any new procedure impeding economic adjustment of returning veterans would be inadvisable. Several causes have contributed to the present overcrowding of German medical schools. There was no deferment of German medical students during the war. The individual medical student received his education in leaps and bounds (educational furloughs). Therefore, at the present time, there are a great number of undergraduate medical students in various stages of education. This number is that much greater because the number of medical students increased appreciably during the war. Finally, far fewer examinations are given in the German medical curriculum than in the medical

curriculum of this country, and, thus, undesirable students are not eliminated. No medical examiner will let a student fail an examination the second time, particularly under pressing economic conditions, if that student has spent six years in the armed forces and from two to four years in a medical school. Most German veterans fall into this group.

RECONSTRUCTION OF GERMAN MEDICAL SCHOOLS

Reconstruction is in progress. Taking 1:1,000 as the optimal physician-patient ratio from both the professional and economic point of view, as well as accepting the present number of physicians as amply sufficient and the period of thirty years as the working time of a German physician, one would need for the American Zone, with its 17,000,000 inhabitants, 17,000 physicians to be replaced every thirty years, i. e., about 566 in one year. With six medical faculties in the American Zone (Erlangen, Frankfurt, Heidelberg, Marburg, München, Würzburg), that figure would require an entry class of about one hundred (100) students each year. The table gives the figures of the approximate number of hospital beds for a teaching hospital with an annual class of one hundred (100) students suggested by our Council on Medical Education and Hospitals as compared with the January 1948 figures of the University Hospitals in the American Zone.

CURRICULUM

German medical educators are interested in starting a reform. They are hesitant in beginning their experiment immediately for the following reasons. At present, graduation from any German medical school is recognized for the whole of Germany, i. e., not only by the different states within each zone of occupation but also by the individual states of all zones. Therefore, for the people of Germany medical licensure is still a keepsake and symbol of a unified Germany. Reform of a single medical school only—so desirable in starting a reform—faces the difficulty that graduates of this school may not obtain the licensure in other German states, but solely from the state in which the medical school is located. It may be added that in the Russian Zone of occupation the three single German states have a much lesser independent status than in the Western Zones and that the so-called German Central Administration in the Soviet Zone (an equal of which does not exist in the Western Zones) faces a much simpler problem. Plans for a reform in the Russian Zone have been published in *Das Deutsche Gesundheitswesen* (1:65-67, 1946; 1:566-568, 1946, and 1:597-600, 1946). It is interesting to note that such an outstanding German scientist as the well known pharmacologist Dr. W. Heubner of Berlin emphasized the similarity between the Russian and the American plans. It may also be pointed out that the Russian military government has a special medical educational section in its organization, which seems to be a constructive agent.

The great problem of medical education in Germany at the present time is the problem of postgraduate training. Attempts for such a program are being made in several places. The newly established exchange program (Chief Civil Affairs Division of the Army, Special Staff, U. S. Army, Washington 25, D. C.) might perhaps be utilized in this connection.

The Unitarian Service Committee, which has sent so many memorable American teaching teams to different European countries, will send one team to Germany this year. German medical educators also hope that it will be possible to establish closer contact with medical institutions of the U. S. Army in Germany.

SULFONAMIDE MIXTURES

To the Editor:—In the July 24 issue of THE JOURNAL there appeared a letter from Dr. David Lehr criticizing the conclusions of Zeller, Hirsh, Sweet and Dowling, who found that the disadvantages of using a mixture of sulfadiazine and sulfamerazine outweigh the advantages. Inasmuch as the article by Zeller and associates seemed to be a valid interpretation of carefully observed clinical phenomena, it is important to evaluate the usefulness of the sulfonamide mixtures from a theoretical point of view.

Although Lehr's observations on the independent solubilities of sulfonamide drugs are widely known and accepted, few persons realize how little there is to gain by using such mixtures. It is relatively simple to calculate just how much extra sulfonamide compound can be dissolved through the use of the mixtures.

Without added alkali, the urine of the average patient with a bacterial infection is rather acid. For the sake of simplicity, let us assume that the pH of the urine is 5.5, its volume 1,500 cc. and that acetylation of the sulfonamide compounds is complete. At pH 5.5, the solubility of the acetylsulfadiazine is 20 mg. per hundred cubic centimeters and the solubility of acetylsulfamerazine is 38 mg. per hundred cubic centimeters (Gilligan, D. R.; Garb, S.; Wheeler, C., and Plummer, N.: *Adjuvant Alkali Therapy in Prevention of Renal Complications from Sulfadiazine*, J. A. M. A. 122:1160, 1943). Therefore, if 3 Gm. each of acetylsulfadiazine and acetylsulfamerazine is excreted per day in 1,500 cc. of urine at pH 5.5, 300 mg. of acetylsulfadiazine and 570 mg. of acetylsulfamerazine will be in solution, while 2,700 mg. of acetylsulfadiazine and 2,430 mg. of acetylsulfamerazine will be in crystalline form. A total of 5,130 mg. of the sulfonamide mixture will be excreted as crystals, whereas if 6 Gm. of acetylsulfadiazine alone were excreted per day, 5,700 mg. would be in crystalline form.

Obviously, the difference between 5,130 and 5,700 is not a very significant one. Therefore, theoretical considerations corroborate the clinical findings of Zeller and associates.

In addition, it should be pointed out that the solubility of acetylsulfadiazine at a pH of 7.5 is 512 mg. per hundred cubic centimeters. Therefore, 7,680 mg. of it could be excreted in solution, without any crystal formation, in 1,500 cc. of urine at pH 7.5.

The use of adjuvant alkali therapy with sulfadiazine alone is a much more effective way of reducing complications from sulfonamide compounds than the use of sulfonamide mixtures.

Medical Motion Pictures

FILM REVIEW

As Others See Us. 16 mm., black and white, sound, 525 feet (1 reel), showing time fifteen minutes. Produced in 1945 by Associated Filmmakers under a grant from the Becton, Dickinson Foundation for the American Hospital Association. Procurable on loan from: Department of Public Relations, American Hospital Association, 18 East Division St., Chicago 10.

This film tends to show the correct and the incorrect manner of receiving a patient on entrance to the hospital and providing for his comfort and care. It portrays the relationship of the hospital personnel with the patient and points out the importance of utilizing tact, kindness and consideration not only at the time of admission but throughout the entire period of hospitalization. There are a few sections in the film which may appear overemphasized; however, it should prove suitable for showing to all hospital personnel.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Privileged Communications: Statements Must Be Pertinent to Treatment.—This was an action by the administratrix of the estate of Edward C. Van Wic, deceased, to recover damages from the United States of America as a result of a collision between a motor vehicle operated by the deceased and a motor vehicle owned and operated by a rural mail carrier employed by the United States. The case was tried in the district court, N. D., Iowa, E. D.

Immediately following the collision the deceased was taken to a hospital at New Hampton, Iowa, and Dr. O'Connor, a practicing physician in that town, was called to attend him. At the trial, Dr. O'Connor was called as a witness by the defendant and was asked on direct examination as to what statements the deceased had made to him in relation to the collision and not connected with his treatment. The plaintiff objected to the testimony called for by the question on the ground that it concerned communications which are privileged under the Iowa law. The court reserved ruling, and Dr. O'Connor was permitted to testify that while the deceased was being treated he made the statement that "he did not see the vehicle which struck him." The question is as to the admissibility of this statement. Section 622.10, Code of Iowa 1946, provides in part as follows: "No practicing . . . physician, surgeon, or the stenographer or confidential clerk of any such person, who obtains such information by reason of his employment, . . . shall be allowed in giving testimony, to disclose any confidential communication properly entrusted to him in his professional capacity, and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice or discipline. Such prohibition shall not apply to cases where the party in whose favor the same is made waives the rights conferred."

The federal courts follow the law of the forum as to communications privileged by state statutes. In the present case, said the court, Dr. O'Connor first saw the decedent in the emergency room at the hospital. He immediately began to administer to him, and the relation of doctor and patient then commenced. The statement in question was made by the deceased while he was being treated and, according to the doctor's testimony, at a time when the deceased was in a mentally clear condition. The statement was not, however, made in response to any question asked by the doctor, and the doctor admitted that the information conveyed by the statement was not necessary for purpose of treatment.

Statements of an injured person to his physician as to matters connected with the occasion out of which the injuries arose and observations by a physician of the patient and of the facts surrounding the injury would seem to stand or fall as privileged communications on their possible relevancy to treatment or on their relevancy as reasonably believed by either the physician or patient or both of them. While it is realized that it is common and natural human behavior for one in recounting a series of events which gave rise to an injury of a certain nature to include much data irrelevant to the ascertainment of the correct type of treatment to be administered, and while it is perhaps desirable that much latitude be allowed these statements as privileged communications to encourage disclosure of all facts necessary for treatment, an extension of the privilege to circumstances related by the patient which could have no possible bearing on the treatment of the injury or other professional service is beyond the plain language of the statute and the most liberal construction of it. It would not seem that whether or not the deceased saw the car which struck him could have any conceivable application to the determination of the proper treatment to be administered to him by Dr. O'Connor. It would not seem that such a revelation by the deceased could possibly have been considered by either communicant as reasonably necessary to the ascertainment of the injuries sustained and the correct treatment thereof. Nor

would it seem that the statement was reasonably incident to any conversation which would bear so directly on the ascertainment of correct treatment as to be included as a part of a whole communication privileged by the statute. The statement was undoubtedly part of the normal reaction of a person in stating or discussing details of an unusual and hazardous incident which had just endangered his life. While the extent of his injuries at the time the statement was made were not fully known, the disclosure in no way could be calculated to bring them to light. In the cases in which the Iowa Supreme Court has held privileged certain statements to or observations by a physician regarding the facts of a mishap from which injuries requiring treatment were sustained, those statements or observations have been interpreted as being necessary to ascertain the proper treatment or the rendering of other professional service, or as having in some degree been regarded by the patient or physician as bearing on such treatment or service. In the present case, said the trial court, the statement in question was in no way necessary to be known in order for Dr. O'Connor to "discharge the functions of his profession according to the usual course of practice and discipline," and the decedent could not have reasonably believed that such a statement could have had pertinency to his treatment. The court therefore held that the statement was not a privileged communication under the Iowa statute in question and it was allowed to be admitted in evidence. The judgment of the trial court was in favor of the plaintiff. *Van Wic v. United States*, 77 F. Supp. 22 (Iowa, 1948).

Dental Practice Acts: Employment by Unlicensed Person as Ground for Revocation of License.—The defendant dentist was charged with a violation of the New Jersey dental practice act and, after a hearing by the state board of registration and examination in dentistry, was found guilty and his license was suspended for six months. This ruling was reversed by the trial court on the ground that the statutory provision under which his license was suspended was unconstitutional, so the state board appealed to the Court of Errors and Appeals of New Jersey.

The dental practice act of New Jersey authorizes the revocation or suspension of a license to practice dentistry if the licensee has been found guilty of having "been employed by an unlicensed manager, proprietor, operator or conductor . . ." The question which we shall answer, said the court, is whether a license to practice dentistry may constitutionally be revoked on a justified finding that the licensee has submitted to employment as a practicing dentist by an unlicensed person. The dental practice act of New Jersey, in addition to the above mentioned provision, also provides that no person shall practice dentistry unless licensed to do so and that any person shall be regarded as practicing dentistry within the meaning of the act who is manager, proprietor, operator or conductor of a place where dental operations are performed. The constitutionality of these latter statutory provisions is not disputed, nor could it well be, the court continued, for the restrictions so imposed upon personal liberty of actions are within the police power of the state to provide for the general welfare of its people and to that end to prescribe all such regulations as in its judgment will secure or tend to secure them against the consequences of ignorance and incapacity as well as of deception and fraud. The practice of dentistry has points of close contact with that of medicine, which has long been the subject of careful supervision and control. Since it is within the power of the state to provide that no unlicensed person shall be the manager, proprietor or conductor of a dental office, continued the Court of Errors and Appeals, it seems to us to be also within the power of the state to provide, conversely, that a licensed dentist shall not be employed in a dental office by an unlicensed manager, proprietor or conductor and to enforce that prohibition by revoking or suspending the license of an offending licensee. Accordingly the court held that the provision of the dental practice act prohibiting employment of a licensed dentist by an unlicensed person was constitutional and that the state board of registration and examination in dentistry was authorized to suspend a license on such a ground.—*Taber v. State Board of Registration & Examination in Dentistry*, 59 A. (2d) 231 (N. J., 1948).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Early Rising After Delivery.—Cornell and Mullen report 1,000 patients admitted to Henrotin Hospital for delivery who represent a typical cross section of postpartum cases. They were allowed up on the sixth day or earlier, 80 per cent being up prior to the fifth day. These patients were in better condition at the time of discharge than if they had remained in bed for eight or more days. They were in a position to adapt themselves more readily to their daily household routine. Episiotomy wound healing was not adversely affected, nor was morbidity increased. No case of thrombophlebitis occurred in those delivered vaginally, which suggests that the tendency toward this complication was reduced. There was no case of uterine prolapse. The rate of involution of the uterus was increased. When necessary, because of overcrowding, the patient could be discharged from the hospital earlier than heretofore with a greater margin of safety. The postoperative course of the 53 cases of cesarean section included in this group was more nearly uneventful. Distention was infrequent. The necessity for catheterization and enemas was lessened when the patient was up to the toilet on the first postoperative day. One case of thrombophlebitis occurred thirty days after operation.

Acute Puerperal Mastitis.—Hesseltine and his co-workers report observations on 210 patients with suppurative puerperal mastitis observed at the Chicago Lying-in Hospital during the last thirteen and one-half years. Six of these patients belonged

to a group of 23 with acute puerperal mastitis treated with penicillin only. In these 6 symptoms had existed from twenty-four to one hundred and forty-four hours before the initiation of the penicillin therapy, whereas the longest period preceding treatment in the 17 nonsuppurative cases was forty hours. All 23 patients became afebrile within forty-eight hours, but this is not proof that the patient has been completely cured, as is shown by the occurrence of abscess in 6 patients during treatment. Penicillin resistance was studied in eleven strains of staphylococci isolated from suppurative mastitis. These grew in the presence of 0.006 to 6.25 units per cubic centimeter of penicillin. A significant proportion of these strains were resistant to the antibiotic, since four grew in at least 3.1 units per cubic centimeter. The local use of ointment containing penicillin on the nipple after nursing failed to affect the incidence of mastitis in postpartum patients. Nasopharyngeal cultures from mothers and babies were examined for *Staphylococcus aureus*. Twenty-one of 30 babies were found to harbor *Staph. aureus* during the first ten days of life, as were 20 of the 30 mothers. Ten of these strains were resistant to 0.5 or more units per cubic centimeter of penicillin in vitro. This resistance would appear to be a factor in the development of suppuration during treatment with penicillin and should be considered in the determination of "adequate" penicillin therapy. Infection of the breast may occur in lactating mothers from the patient herself or from the nursing infant. Although the importance of the nasopharynx is suggested, other possible sources of infection must be recognized. Late treatment, the resistance of some staphylococcus strains to penicillin and the localizing effect of the inflammatory tissue would seem to contribute to the progression of the disease process to suppuration. Increased dosage of penicillin seems desirable for infections with organisms of higher than usual resistance to the antibiotic.

Spinal Anesthesia in Obstetrics.—Andros and his co-workers practiced saddle block anesthesia in 719 parturient women between the ages of 18 and 42 years, at the Chicago Lying-in Hospital, during the first four months of 1947. The majority of the injections were made with the patient in her labor bed, placed in a sitting position over the side of the bed, bending forward and supported by an assistant. Spinal puncture was made at the level of the fourth lumbar interspace. The anesthetic agents used were difucaine hydrochloride in 514 instances, tetracaine hydrochloride in 115 cases, procaine hydrochloride in 27 and "metycaine hydrochloride" in 47. Seven additional patients received butethamine formate ("mono-caine formate"). In 24 of the 719 cases (3.3 per cent) there was failure to obtain anesthesia. Fourteen of these failures were converted to successes by repetition of the tap and the injection. In this series of 709 patients successfully anesthetized there were 346 primiparas and 363 multiparas. Anesthesia was instituted at 5 or 6 cm. of cervical dilatation in multiparas and near 8 cm. in primiparas. Other prerequisites to saddle block should be progressive labor, an effaced cervix, fixation of the fetal head and no cephalopelvic disproportion. The usual duration of complete uterine analgesia obtained from procaine hydrochloride and "metycaine" was from sixty to ninety minutes, with perineal anesthesia usually lasting nearly two hours. Tetracaine generally gave uterine analgesia of ninety to one hundred and five minutes, and perineal anesthesia between two and two and one-half hours. Only single blocks were used in the great majority of patients. Excluding the 14 patients receiving two taps for a single successful anesthetic, there were 65 patients who received the benefits of two or three successful injections; these patients were carried under saddle block anesthesia from three hours to slightly less than nine hours when delivery was completed. The procedure has been found to be safe, simple and precise. The degree of success has been high. The rate of operative intervention in delivery was not significantly increased. Complications attributable to the anesthetic procedure have not been a problem. The benefits to the fetus in early spontaneous respiration have been striking. There has been no increase in the fetal or maternal morbidity or mortality.

Solar Retinitis Due to Exposure During Eclipse.

Tower says that within two weeks following a recent solar eclipse, 8 children presented themselves at the eye department of Yale Street Health Center with signs of retinal injury to the region of the macula, due to exposure to the sun. The symptoms of solar retinitis are a persistent after-image, positive scotoma and metamorphosia. Visual acuity is reduced. Ophthalmoscopic examination at first may reveal no abnormality or only a pale spot at the fovea centralis surrounded by a brownish ring. Subsequently, a translucent gray spot, suggestive of congestion and surrounded by a darker ring, may become visible in the center of the macula lutea. The pigment deposits become more pronounced and form a circular stippled area of gray around the fovea centralis. The damage proved to be irreversible in all children. Vision had not returned to its previous state after a lapse of several months. Neither smoked glasses nor photographic film afford sufficient protection for observing an eclipse. Ordinary sun glasses, when used for looking into the sun, transmit infra-red rays. The incidence of solar retinitis decreases with advancing age; school children are most likely to experience macular injury following observation of an eclipse.

Growth Patterns of Allergic Children.—Cohen and Abram raise the question of the existence of fundamental characteristics which distinguish allergic persons from the general population and their hereditary patterns. Previous studies have indicated that the allergic child is likely to be retarded, short for his age and light for his height when compared with average standards for height and weight. This has been thought to be due to the effects of the disease on appetite or to some actual disturbance in the utilization of food associated with the disease. It is possible that allergy occurs in children who have physical potentialities as regards body type and growth different from those of the nonallergic population, but until recently there have been no satisfactory methods for studying these possibilities.

The grid technic described by Wetzel makes such a study possible. From 503 observations on 150 allergic children seen in private practice compared with 622 observations on 102 non-allergic controls studied by the grid method, the authors draw the following conclusions: 1. Allergy occurs more frequently in children (especially boys) who, by inheritance, are constitutionally slender. 2. Allergy is a common cause of growth failure. 3. Control of active allergy is accompanied by a corresponding growth repair provided an adequate diet is available.

Effect of Arteriosclerosis on Hypertension in the Aged.—Zeman and Schwartz made blood pressure studies on 150 elderly persons and correlated them with the findings at necropsy. Factors influencing blood pressure are evaluated with emphasis on the effect of the sclerotic aorta and its branches in producing the low diastolic pressures often found in aged persons. The patients were residents of the Home for Aged and Infirm Hebrews of New York City. The series included 66 men and 83 women, ranging in age from 60 years to 92 years. The patients were observed from a few days to twenty years. Blood pressure is mainly determined by four variables: the cardiac output, peripheral resistance, aortic elasticity and capacity. As age advances, there is a tendency for peripheral resistance to increase, for aortic elasticity to decrease, for aortic volume to increase and for cardiac output to decrease. A "normal" blood pressure in old age is not evidence of a normal cardiovascular system, but is the result of several of the aforementioned factors acting in opposite directions. Systolic hypertension is not to be sharply distinguished as a special form of elevated blood pressure, entirely normal for old age, and benign. Many cases of so-called systolic hypertension are in reality a form of systolic-diastolic hypertension in the sense that peripheral resistance is increased, but

the level of diastolic pressure is modified by changes in the great vessels. Systolic and diastolic hypertension in old age appears to make the persons who manifest it more liable to cerebral accidents and adds a burden to the heart. Malignant hypertension is rarely, if ever, observed in the aged. The level of blood pressure in old age should be supplemented by studies to determine the cardiac, cerebral and renal function and the degree of elasticity and dilatation of the aorta. Physiologic measurements of the cardiac output and peripheral resistance would be particularly desirable.

Transorbital Lobotomy.—Freeman reports 10 cases of transorbital lobotomy followed for two years. There was 1 instance of left hemiparesis of four days' duration with complete recovery of power on that side. Later this patient had epileptic seizures. The other 9 patients suffered no ill effects. One of the patients died twenty months after operation of carcinoma of the pancreas. Of the 9 living patients, 5 are keeping house, 2 are employed, 1 is living at home and 1 relapsed eighteen months later. Transorbital lobotomy has a place in the treatment of mental disorders somewhere between shock therapy and major frontal lobotomy. It is to be considered in the case of schizophrenic patients who have been sick less than a year and who respond unfavorably to shock therapy. It may be tried in cases of involutional depression with agitation when shock therapy fails. If transorbital lobotomy produces only temporary results, standard frontal lobotomy may give permanent relief. Transorbital lobotomy does not seem to produce the undesirable effects that sometimes follow frontal lobotomy. Part of this is due to the less extensive character of the operation.

Peritoneal Irrigation in Uremia.—Allbee and Mayfield treated 1 man aged 45 who had uremia due to acute renal failure of undetermined cause by peritoneal irrigation, using Ringer's solution and later distilled water and 5 per cent dextrose. Irrigation was instituted after patient had been anuric for nine days. It was continued for ten days; on the tenth day the kidneys had a twenty-four hour output of 1,700 cc. This method provided a substitute for the function of the kidneys by keeping the nitrogenous products from increasing and by even decreasing them a little over this ten day period until the damaged kidneys could regain function. The technical aspects of the method did not prove to be difficult, and there was no peritonitis of note. Peritoneal irrigation was a life-saving measure in this case; it is recommended that it be tried in similar cases.

Severe Nasal Congestion Following Use of Nose Drops.—Talmage reports the case of a woman, aged 62, who came to him complaining that her "nose was blocking up" continually. More than a year before, a specialist had prescribed a 0.1 per cent solution of naphazoline hydrochloride. The brand used was "privine hydrochloride" (N. N. R.), which was available in 0.1 per cent and 0.05 per cent solutions. The manufacturers advised that only the weaker solution should be used when prescribed for self application. In this case, it was intended for use during an acute infection of the upper respiratory tract, and the stronger (0.1 per cent) solution was prescribed. The patient continued the drops long after original need for them

should have disappeared. For more than a year she had been using 1 ounce a week. Her eyelids were puffy. Nasal mucosa and turbinates were red and extremely dry but appeared unusually congested and swollen. Believing that the long-continued use of the naphazoline might account for the nasal congestion and nervousness, the author instructed her to discontinue the nose drops. The feeling of apprehension and dependence on the naphazoline completely subsided after three weeks. The author mentions others who have observed numerous patients whose nasal congestion had been aggravated or maintained by naphazoline. Vasodilatation is probably a compensatory reaction to the initial vasoconstriction produced by this drug.

Diagnosis of Jaundice.—According to Steigmann and Popper, one of the main pitfalls in the differential diagnosis of jaundice is presented by primary hepatitis with intrahepatic arrest of bile flow. In these patients, the clay-colored stools, although usually pointing to "surgical" jaundice, are due not to any mechanical obstruction in the extrahepatic bile passages but to some pathologic changes within the liver itself—"medical" jaundice. The absence of bile from the intestine is established by examination of the feces and urine on consecutive days. In a series of 212 patients with jaundice due to hepatitis, 36 (17 per cent) failed to show urobilinogen in their urine or feces for three to forty-one days, with an average of eleven days. This phenomenon was found in all age groups, although it was predominantly encountered in patients between 40 and 50 years of age. The absence of bile from the intestine appears to be somewhat more common in the toxic than in the infectious type of hepatitis. It seems frequently to be encountered in cases of hepatitis following arsenical injections and after ingestion of cinchophen. In cases of cirrhosis complicated by acute damage to the liver, it may be an additional complicating fac-

tor. Awareness of this condition and careful and prolonged observation of patients with hepatitis with this phenomenon, by clinical and laboratory means, will ultimately lead to correct diagnosis and management. It is advisable to do an exploratory operation in any patient with prolonged arrest of bile flow in whom the slightest possibility of an extrahepatic obstruction remains. The possible mechanisms for intrahepatic arrest of bile flow are actual obstruction in the region of the canal of Hering in some, and functional changes in the terminal bile ducts in other cases.

Abdominal Epilepsy.—Moore reports 3 cases of abdominal epilepsy with paroxysmal abdominal pain and disturbed motility of the gastrointestinal tract in women aged 50 and 32 and in a boy aged 12 who showed satisfactory response when placed on anticonvulsant therapy. Each of the cases satisfied either all or most of the following criteria necessary to establish the diagnosis of abdominal epilepsy: (1) the patients must be examined by all available methods to rule out intrinsic disease of the pelvic, abdominal and thoracic viscera, morbid involvement of the spinal cord or peripheral nerves and psychosomatic projection mechanisms; (2) historical data regarding the possible existence of cerebral disease or dysfunction should be uncovered; (3) the behavioristic occurrence of the pain should adhere to the pattern of epilepsy; (4) the presence of associated epileptic phenomena, either preceding or during the episodes of abdominal pain, will form corroborative evidence of the nature of the disorder; (5) positive neurologic signs and findings from laboratory studies including cytologic and chemical, roentgenologic studies of the skull and electroencephalographic studies, indicating the existence of a cerebral structural or physiologic disorder, should be in evidence; (6) favorable effects of anticonvulsant drugs on the occurrence of abdominal pain and/or abnormal gastrointestinal motility should be exhibited, and the influence of these drugs on the electroencephalogram should in most instances parallel the clinical results. Absence of abnormal cerebral discharge as observed in the electroencephalogram may be encountered in patients with abdominal epilepsy as in epilepsy of all types.

Multiple Calcinosis with Hypervitaminosis D.—McLean and Lebo review the history of a man, aged 56, who was first seen by them in April 1945, when he complained of tiredness, loss of weight, lack of concentration, urinary frequency, insomnia, and pain in the neck, shoulders, knees, ankles and feet. He had been treated for hypothyroidism, prostatitis and arthritis. He had taken six capsules daily for the previous two and a half years, or a total of 150,000 international units of vitamin D

and 180,000 units of vitamin A daily. One month before, he had noticed a lump appearing in his right gluteal region, and about the same time painful swellings of his left ring finger, thumb and wrist. Incision into the right gluteal region exposed multilocular cysts which contained a chalky material. The cyst on the left ring finger was also incised and the same type of material was obtained. The presence of calcium was ascertained. Withdrawal of vitamin D was followed by disappearance of symptoms. The authors feel that this is a case of renal insufficiency, anemia and metastatic calcinosis caused by excessive vitamin D therapy. If severe toxic manifestations of vitamin D poisoning are to be avoided, the patients must be subjected to closer observations, periodic laboratory and roentgen examinations and to questions as to whether they are taking vitamin therapy, especially those patients having an unexplainable renal insufficiency, anemia, or calcific deposits in the blood vessels or soft tissues.

Venereal Granulomas.—Wilson lists the total number of cases of chancroid, granuloma inguinale and lymphogranuloma venereum reported to the Florida State Board of Health from January 1942 to August 1947. Florida had 12.4 per cent of the cases of granuloma inguinale reported in the entire country. Laboratory studies and intradermal tests have their limitations in the diagnosis of diseases of this group, but they play an important part in the differential diagnosis. Penicillin has no specific antibiotic action on the etiologic agents in these three diseases. Streptomycin is the most encouraging form of therapy for the rapid healing of patients with granuloma inguinale; this method of treatment has been successful when other methods have failed. Although streptomycin is expensive, the rapid healing it produces and the fact that it aids in the control of this disease seems to justify the expenditure. Sulfathiazole was the drug of choice in the medical treatment of chancroid and lymphogranuloma venereum.

Myotonia Acquisita Cured by Cholecystectomy.—According to Puppel and Kline myotonia acquisita is a rare muscular disorder characterized by increased muscular irritability and contractility associated with diminution in the power of relaxation. It constitutes a syndrome which includes the

myotonic disorder of movement with stiffness, tension and spasm in the voluntary muscles when movements are initiated, the myotonic reaction with normal mechanical and electrical excitability of the motor nerves, but an increased mechanical and electrical excitability of the muscles, and muscular hypertrophy. The acquired form (myotonia acquisita or Talma's disease) has been differentiated from the congenital form (myotonia congenita or Thomsen's disease) although these may be manifestations of the same pathologic process, which, however, is not fully understood. The acquired form has been described after trauma, dysentery, gastroenteritis, alcoholism, lead poisoning, tuberculosis, and typhoid. Although the disease tends to improve spontaneously, search for the causal factor may be advisable in order to reduce the duration and the severity of the process. The authors present a detailed history of a woman in whom myotonia apparently followed chronic calculous cholecystitis with an associated chronic hepatitis and was cured after cholecystectomy, choledochostomy and adequate treatment of the hepatitis.

Herpes Zoster and Abdominal Symptoms.—Boshier and Williams say that, although investigators have pointed out that herpes zoster may mimic intra-abdominal disorders, the close simulation of conditions requiring surgical intervention is not appreciated. The authors report the case of a 15 year old boy who was admitted to the hospital with a presumptive diagnosis of perinephric abscess in which the diagnosis of segmental neuralgia seemed justified. There was tenderness in the left lower quadrant, flank and costovertebral angle. The tenderness did not increase on deep palpation. It was still present on examination with the abdominal muscles tensed, thus indicating that most of the pain at least was parietal (positive Carnett's sign). After an intercostal nerve block in the region of the tenth and eleventh thoracic nerves posteriorly, the pain and hyperesthesia disappeared. The authors report 2 other cases simulating surgical disease in which there was evidence of herpes zoster. In the first of these, the additional diagnosis of appendicitis was made; a posterior intercostal nerve block would have permitted more accurate evaluation of the apparent deep evaluation of the apparent deep tenderness. The application of Carnett's test, that is, palpation with the abdominal musculature tense, would probably have suggested that the pain and tenderness were predominantly parietal. In the second case, the long interval of ten days between the onset of symptoms and the appearance of the rash postponed the correct diagnosis. The authors stress that Carnett's test is a useful adjuvant in the examination of a patient with abdominal pain.

Vitamin D₂ in Cutaneous Tuberculosis.—The principle of the treatment in which Charpy of Dijon, France, has been interested for the past seven years consists in administering chemically pure vitamin D₂ by mouth in alcoholic solution, in single doses of 15 mg. (600,000 international units), repeated from twice to once a week during many consecutive months. The author reviews personal experience during six years in regard to 150 cases of tuberculous lupus followed from beginning to end and about 60 other cases followed periodically. Vitamin D₂ therapy has changed the usual prognosis of lupus vulgaris. In the favorable cases the therapy influences the inflammatory reaction in the skin. The tuberculous infiltrations, the lupomas, are the most resistant elements. They become paler, but it takes weeks or even months before they disintegrate, separate and finally disappear. It is exceptional to be obliged to supplement the internal treatment by local destruction of residual lupomas. Excellent results are obtained in ulcerated lupus; a little slower in the tumid forms and in the edematous and congestive type; slower still in the erythematonodular lupus ruber planus. Lesions in the mucous membrane disappear rapidly. Adenitis and lymphangitis disappear for the most part during treatment. It is sometimes useful to puncture "cold" abscesses. The therapeutic effect should always be detectable from the beginning of the treatment and should become obvious by the fifteenth day. Should there be no result at that time, lack of absorption, biliary insufficiency, inadequate tissue permeability through an excess of sodium chloride, or the coexistence of syphilis must be considered as factors that may be responsible for the failure of the treatment. Skeptics, although conceding amelioration of lupus, have questioned actual cures, but the author insists that he has seen many patients in whom cure has persisted for three to five years.

Feminism Due to Carcinoma of Adrenal Cortex.—Armstrong and Simpson review 8 previously reported cases of feminism due to carcinoma of the adrenal cortex and describe a case of their own in a policeman aged 40. In this case laparotomy disclosed a large adherent and necrotic tumor above the left kidney. Because of the vascularity of the tumor mass, its size and extensive adhesions, no attempt was made to remove it. Subsequently the patient deteriorated rapidly; he became emaciated, jaundiced and ascitic, and his liver became enlarged and nodular. Death occurred some eleven months from the onset of his symptoms. There was terminal hematuria. Acquired feminism due to carcinoma of the adrenal cortex causes a well defined syndrome of gynecomastia, abdominal tumor, atrophy of the external genitalia and loss of libido and

potency. The condition is rapidly fatal, especially in younger patients. Biochemically there are a moderate excess of urinary androgens and a gross excess of estrogens. A most striking feature is the invariable presence of a palpable abdominal tumor. The possibility that feminism might be due to hyperplasia of the adrenal cortex has been suggested by Broster and Vines, who have clearly shown that virilism can be due to hyperplasia of the adrenal cortex as well as to carcinoma or adenoma. They consider, that, similarly, feminism may be due to hyperplasia of the adrenal cortex.

Virilizing Tumors of the Ovary.—Searle and his associates report the case of a woman, aged 33, who showed signs of virilism during pregnancy, particularly change in voice and hirsuties. These changes had become especially noticeable after twenty-four weeks of gestation. The patient delivered a normal child. Some weeks after delivery, the abdomen was opened and a cystic mass was found lying anteriorly to the right broad ligament. A long pedicle had evidently allowed considerable "wandering," and the cyst had finally "jumped" the broad ligament. The cyst was excised. The authors believe that this is the only reported case of an adrenal-like ovarian tumor appearing and causing virilism during pregnancy. Most of the signs of virilism have retrogressed notably since the removal of the tumor. The change in voice, however, remains more or less unaltered. This results from irreversible structural changes in the vocal cords. The ovarian tumor falls into the adrenal-like group. There is no evidence to assess it as a true arrhenoblastoma.

- *Myocardial Lesions in Hyperthyroidism. U. Lemos Torres.—p. 525.
*New Treatment of Barbituric Coma. A. Louzada.—p. 611.

Myocardial Lesions in Hyperthyroidism.—Lemos Torres found, at necropsy on 3 patients who died from congestive cardiac insufficiency and toxic crisis after thyroidectomy for toxic goiter, a serous inflammation of the myocardium in the first patient, which progressed to a fibrosis in the second patient and later to fibroblastic myocarditis, as seen in the third patient. Progressive serous inflammation and the consequent fibroblastic myocarditis are typical of hyperthyroidism.

New Treatment of Barbituric Coma.—Louzada regards picrotoxin as the treatment of choice of barbituric coma. Good results in 2 grave cases are reported from intravenous administration of the drug. The treatment was begun ten hours after ingestion of 46 tablets of 0.1 mg. of "seconal sodium" each. Picrotoxin was given in doses of 21 mg. during the first five minutes, 45 mg. ten minutes later and 30 mg. every hour for eight consecutive hours, followed by three more injections, in doses of 15 mg. each, every three hours up to a total amount of 585 mg. for the whole treatment, which lasted thirty-five hours. The patient should be given intravenous injections of dextrose solution or of sodium chloride solution and of 15 cc. of nikethamide, 10 mg. of adrenal cortex extract, 100 cc. of sodium bicarbonate solution and inhalations of oxygen.

- !Tuberculosis After Treatment with Streptomycin. M. Straub and H. E. Schornagel.—p. 832.
Course of Tuberculous Meningitis Under Influence of Streptomycin. A. Verjaal.—p. 841.

Tuberculosis After Treatment with Streptomycin.—Straub and Schornagel describe manifestations of recovery in 4 patients with tuberculous meningitis who were treated with streptomycin, but who died in spite of the treatment. Streptomycin apparently can cure the acute exudative dissemination of tuberculosis before this has assumed the specific histologic character. This is proved by the leptomenigeal changes, the tuberculous primary focus and the acute miliary tubercle. Streptomycin has no distinct influence on productive tuberculous changes, not even on subacute miliary dissemination. These, however, are kept in check by the body itself. Streptomycin, by curing acute exacerbations, gives a chance to the natural defensive power of the body to overcome the disease.

- Hemorrhages During and After Placental Stage of Labor, Their Frequency nad Prevention. H. Sauramo.—p. 399.
Interstitial Pregnancy. N. Clemetsen.—p. 403.
*Some Virus Diseases During Pregnancy and Their Effect on Fetus. H. Grönvall and P. Selander.—p. 409.
*Rubella During Pregnancy and Congenital Defects in Child. M. Zewi.—p. 416.
Full Term Pregnancy with Syncopal Attacks in Dorsal Position. N. Clemetsen.—p. 422.

Virus Diseases and Their Effect on Fetus.—Grönvall and Selander's investigations show that maternal German measles, mumps, acute hepatitis and acute anterior poliomyelitis can be fraught with danger for the fetus. German measles in pregnancy has been less dangerous for the fetus in Sweden than in Australia.

Rubella During Pregnancy and Congenital Defects in Child.—In Zewi's 2 cases from Finland in infants whose mothers had German measles in the first and second months of pregnancy, respectively, there were bilateral congenital cataracts, with microphthalmia in one; in the other, bilateral congenital hydrophthalmus; in both, congenital heart defect. The weight at birth was low; the infants had difficulty in taking nourishment, and their physical and mental development was retarded.

- *Penicillin Treatment in Acute Osteomyelitis: Primary Results. E. Eliassen.—p. 466.
*Late Results After Sulfonamide Treatment in Purulent Meningitis. M. F. Hauge.—p. 469.
Thrombocytopenia After Quinidine Medication: Tetany and Myocardial Injury. J. Burstein and B. A. Lamberg.—p. 473.
*Curare in Treatment of Poliomyelitis. N. Normann.—p. 476.
Prostigmine in Acute Porphyria. R. Gordin.—p. 480.
Circulatory Disturbances After Gynergen Treatment. A. Hjertaas.—p. 481.

Penicillin Treatment in Acute Osteomyelitis.—Eliassen gives single massive doses of penicillin (100,000 to 200,000 units) twice a day till the acute stage is past and the patient is afebrile. Roentgenologic examinations afford guidance for the continued treatment. The treatment should be started as early as possible, even on suspected diagnosis of acute osteomyelitis. The essential factor in treatment of this disease with penicillin is believed to be sufficiently long duration of the treatment. In 7 of the 8 cases in which treatment was given during the last year the process seems to have been completely arrested and reparation to be in progress; in 1 case extensive sequestration and fistula formation occurred.

Late Results After Sulfonamide Treatment in Purulent Meningitis.—Of 108 patients with the disease treated with sulfonamide drugs by the mouth and/or with parenteral injection, 27 died. On follow-up of the surviving 81 patients from one half to eight years after discharge, Hauge found permanent organic defects in 10 and permanent psychoneurasthenic defects in 28; of the 66 patients with meningococcal meningitis 7 had permanent organic defects and 16 permanent psychoneurasthenic defects. Sulfonamide treatment of purulent meningitis has not reduced the percentage of permanent and grave defects or milder and transient defects parallel with the mortality, and the late prognosis must be viewed with reservation. It is probable that the more promptly the treatment is started the greater the chance of avoiding defects.

Curare Treatment of Poliomyelitis.—Normann says that curare, tried in 12 cases of poliomyelitis in the acute stage and in 6 in a later stage, was of no definite value in the acute phase but gave good results in 3 of the 4 cases with beginning contractures. Side effects in some instances indicated termination of the treatment. The dosage should be individualized because of the danger of overdosage, as in cases with involvement of the respiratory tract. No conclusion could be drawn as to the efficacy of curare in combination with more radical physical therapy.

Asthma in Norway. Statistics on Occurrence and Significance. O. Clausen.—p. 525.
Rash in Mumps. Report from Practice. A. Perdrup.—p. 530.

Treatment of Vesical Tumors.—On the basis of 183 patients treated from 1940 to 1947, one third of whom had benign papillomas, one third malignant papillomas and one third cancer without early papillomatous stage, Strömbeck proposes the following plan: (1) in papillomas of benign type, if small and solitary, transurethral electrocoagulation; if larger and solitary, open electroexcision, possibly with implantation of radium needles, and in papillomatosis, extirpation of the bladder; (2) in papillomas of malignant type, if solitary, electroexcision with implantation of radium needles, and secondary extirpation of the bladder in recurrence; if larger and multiple, primary extirpation of the bladder; (3) in cancer, total extirpation of the bladder, and where this is contraindicated, resection or electroexcision with implantation of radium needles, with care not to make resection or excision too small because of reliance on the radium adjuvant; (4) possible preoperative and postoperative roentgen treatment, and (5) regular control of patients treated without cystectomy so that more effective methods can be employed early in case of possible recurrence.

Book Notices

Cancer: A Handbook for Dentists. Prepared by the Tumor Committee of the Connecticut State Dental Society. Cloth. Pp. 52, with 63 illustrations. Connecticut State Department of Health, Hartford, Conn., 1918.

Connecticut is among the best organized of all of the states in its approach to the problem of cancer. The attack on cancer must be total. Every one of the healing professions is concerned in the earliest possible detection of the symptoms of this disease. The handbook here reviewed is a product of a special committee and is circulated through the Connecticut State Department of Health and the Connecticut State Dental Association. It is magnificently illustrated with black and white and colored illustrations which portray graphically the conditions for which the dentist should be continually observant.

A Research in Marriage. By G. V. Hamilton, M.D. Cloth. Price, \$5. Pp. 571. Lear Publishers, 105 E. 15th St., New York 3, 1918.

This is a study on the sexual and a few other aspects of marriage based on a survey of one hundred couples. It is like the Kinsey Report in some ways but unlike it in others. The numbers are much smaller than those on which Kinsey reports. The investigation was based on cards of questions, each subject being examined separately in the private consulting room of the author. Questions were not asked orally, but were presented on the typed cards, of which forty-seven were used for each woman and forty-three for each man. The cards were passed to each subject and the answers were recorded together with notes on significant behavior reactions on the part of the subjects. The results are presented in tabular and narrative form. The author is guarded in his interpretation and conclusions.

The Practitioners' Card Index Guide to Treatment. Boxed. Devereaux (Medical) Publications Limited, 36-37 Maiden Lane, Strand, London, W. C. 2, [n. d.].

This is an attempt to present the new and practical methods of therapeutics in the form of an alphabetic card index. Techniques, dosage and methodology of treatment with the newer drugs are given in summary form, and many of the cards carry ready references to recent literature for more details. It is the stated intention of the authors to evolve a system that shall become increasingly comprehensive. For this purpose constructive criticism of subscribers has been requested. When fully developed, the card index guide should offer a useful and ready reference for the busy practitioner, particularly if it is kept up to date by frequent review of the newer developments in treatment.

No Retreat from Reason and Other Essays. By Alfred E. Cohn. Cloth. Price, \$3.50. Pp. 279. Harcourt, Brace & Co., 383 Madison Ave., New York 17, 1948.

Here are a variety of essays which the author has written over the years. Most interesting are his biographic studies of John Wyckoff and Simon Flexner. In these essays the author reveals himself as a philosopher with an intimate knowledge of art, music and letters. The essays are stimulating, in many instances lightened with wit and humor, and epigrams worthy of quotation. The essay called "On Retiring" is a somewhat cynical comment on an automatic retiring age, quoting great numbers of men who accomplished intellectual marvels beyond the age of 60.

Bases del control sobre la verruga. Por el Dr. Guillermo Gorblitz. Prólogo Dr. Sergio Bernales. Paper. Pp. 55, with 6 illustrations. Corporación peruana del santa, Servicio médico, Lima, Peru, 1947.

This comprises a survey of the epidemiologic problem of bartonellosis (verruca peruana) in Peru, including historical considerations, geographic distribution, vectors and factors important in its control. The importance and usefulness of D.D.T. (4,4'-dichlorodiphenyltrichloroethene) in the control of this disease so far is emphasized and the promise that this drug brings for future more complete control of the disease in Peru is discussed in detail. Several excellent plates, charts, and other illustrative material are included.

An Educational Philosophy for Exceptional Children. Proceedings of the Spring Conference on Education and the Exceptional Child of the Child Research Clinic of The Woods Schools, A Private School for Exceptional Children, Langhorne, Pa., May, 1947. Paper. Pp. 53. Child Research Clinic, The Woods Schools, Langhorne, Pa., 1947.

This brochure contains papers delivered in a symposium at the Woods School in May 1947. Similar conferences and institutes have been conducted at this institution on subjects dealing with the education of the exceptional child each spring and autumn since 1935. The introductory remarks are by Dr. George S. Stevenson, Medical Director, National Committee for Mental Hygiene. The following papers are included: "Theories of Culture and the Deviant," Morris Edward Opler, Ph.D.; "Education as a Factor in Personal Adjustment," Lawson G. Lowrey, M.D.; "Today's Changing Educational Scene," W. Carson Ryan, Ph.D.; "The Importance of Pattern Movements in the Rehabilitation of Cerebral Palsy Patients," Temple Fay, M.D.; "Communication as an Essential Area of Learning," Emmett Albert Betts, Ph.D., and "Modern Woman and the Harvard Report," O. Hobart Mower, Ph.D.

While each speaker dealt with the problem in relation to his own field, all were concerned with the role of education in aiding the individual to develop his potentialities fully. This booklet will be of interest to all physicians whose work touches on the educational and adjustment problems of the exceptional child.

The Biological Standardisation of the Vitamins. By Katharine H. Coward, D.Sc., Head of the Nutrition Department, Pharmaceutical Society of Great Britain, London. Second edition. Cloth. Price, \$5. Pp. 224, with illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This book is devoted to a detailed description of the methods used for the biologic assay of certain vitamins. Assay procedures for vitamins A, B, C, D and E are given but because of the increasing use of microbiologic and chemical techniques, some of these now have only historical value or are useful only under special circumstances. Nearly one fourth of the book is devoted to a consideration of statistical methods applicable to the assays discussed in the first part. This discussion is probably the most valuable portion of the book. Nevertheless, this volume has limited usefulness but may be of interest to those engaged in routine bioassay work.

Physiologic Therapy in Respiratory Diseases. By Alvan L. Barach, M.D., Associate Professor of Clinical Medicine, Columbia College of Physicians and Surgeons, New York. Second edition. Fabrikoid. Price, \$9. Pp. 408, with 74 illustrations. J. B. Lippincott Co., 227-231 S. Sixth St., Philadelphia 5, 1948.

The first edition of this valuable book was written in 1944 and titled, "Principles and Practices of Inhalational Therapy." So much new knowledge has been contributed since the first edition was written that this second addition was needed. The subject matter is clearly presented and easy to read. The author correlates the pathologic physiology of each disease entity with the physiologic principles which underlie the treatment of the condition by inhalation therapy and other procedures which have value in the management of respiratory diseases. The book is recommended to any one who desires to know the indications and rationale of the physiologic therapy of the disorders of breathing.

Interesting and Useful Medical Statistics. Edited by William H. Kupper, M.D. Cloth. Price, \$6.50. Pp. 528. Wm. C. Brown Co., 915 Main St., Dubuque, Iowa, 1948.

This remarkable book consists of reprintings of hundreds of tabulations of numerical data from American medical publications since about 1935. The tables are arranged alphabetically according to subject, and an index facilitates the reader's search for information. The source of each table is stated, and is generally a readily available recent American publication. If prospective readers will remember that the book ignores all foreign literature and all publications before 1935, deals only with periodic literature, is unsystematic and uncritical, makes no mention of other similar works already published (such as the scholarly "Daten und Tabellen für Mediziner" by Vierordt) and expects the reader to look up the context of the tables for himself, this book can be extremely useful to writers and lecturers.

Old Age: Its Compensations and Rewards. By A. L. Vischer, Dr. Med. Foreword by Lord Amulree, M.D., F.R.C.P. Second edition. Cloth. Price, \$3.50. Pp. 200, with 9 illustrations. The Macmillan Co., 60 Fifth Ave., New York 11, 1947.

Since Dr. Vischer has been for more than twenty years director of the Municipal Home for the Aged in Basle, Switzerland, he can speak with real authority on the subject of old age. In this book he covers a great deal of ground.

Part I is devoted to a consideration of senescence as a bodily and mental process. Part II deals with the duration of life, under the headings "The Chronological and Physiological Stages of Life"; "The Centenarians"; "Old Age and Longevity in the Animal World"; "Prolongation of Life and Rejuvenation," and "Maladies of Old Age, and the Care of the Aged."

In Part III—"Society and the Individual; Their Attitude Toward Old Age"—Dr. Vischer discusses old age in other civilizations; the relation between the older and younger generations; the achievements of old age, and, finally, the personal attitude toward old age. This section, particularly the final chapter, is the best part of the book. Evidently Dr. Vischer is expressing his own philosophy when he outlines "the personal attitude toward old age," and he is to be congratulated on having achieved the frame of mind that would enable him to say: "old people who remain intellectually active often wear better physically. . . . The secret of the good life in old age lies in the possibility of bringing the mode of life and the chronological phase into harmony, like a well-broken pair of horses . . . with a correct attitude to youth the old man may even come to realize that intercourse with youth can only bring him profit. . . . The dread of overworking is very seldom justified. . . . We . . . want to prolong not only life, but also achievement."

Diseases of the Chest Described for Students and Practitioners. By Robert Coope, M.D., B.Sc., F.R.C.P., Hon. Physician, Royal Liverpool United Hospital (Liverpool Royal Infirmary). With a foreword by Lord Horder. Second edition. Cloth. Price, \$7.50. Pp. 541, with 168 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

The chief revision in this the second edition of this book is in the bronchopulmonary anatomy, which has been brought to conform more closely to the modern American concept emphasizing the bronchopulmonary segments. The book is apparently written primarily for the medical student in the clinical years. Much space is devoted to physiology and to symptoms and physical signs with mechanisms of their production. The discussion of tuberculosis is very good except that streptomycin is not mentioned. The chapter on bronchial carcinoma is excellent, and the drawing illustrating the metastatic sites is especially illuminating. The discussion of fungous diseases is inadequate, and histoplasmosis is not even mentioned. There is a paucity of roentgenograms which is refreshingly at variance with the recent American tendency to make the literature on the chest top-heavy with them. The author endeavors "to set forth how diseases of the chest should be taught." He has produced a book which is excellent for the undergraduate and helpful to those in actual practice. The style is pleasing and, all things considered, the volume is well worth while to any one interested.

Recent Progress in Hormone Research: The Proceedings of the Laurentian Hormone Conference [1946]. Volume II. Edited by Gregory Pincus. Committee on Arrangements: R. W. Bates, R. D. H. Heard and G. Pincus. Cloth. Price, \$8. Pp. 427, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1948.

This is the second volume of what promises to be a valuable annual contribution to the literature on endocrinology. Following the pattern established by the first volume, the present book presents the papers and discussions given at the 1946 Laurentian Hormone Conference. The first two reports in the book present a stimulating discussion of the new physical-chemical assay methods for estrogenic hormones. At last it appears likely that quantitative chemical assays may replace laborious and costly biologic determinations of the estrogens, and that the various types of estrogens can be separated and quantitatively determined. The section on pituitary control and activity deals largely with pituitary-adrenal relationships, with the luteinizing hormone and with the hormonal control of

lactation. The last-named subject is particularly well presented by W. E. Petersen. Hormone metabolism receives attention in two papers, one by Roy Hertz and the other by Ralph I. Dorfman. Although the papers are confined to estrogens and androgens, considerable light is thrown on the metabolism of other steroids. Hormonal regulation of metabolism is discussed from the standpoint of insulin secretion, relation of thyroid activity to diabetes and the actions of the toxic thioureas. Finally, the clinical aspects of endocrinology are presented in reports dealing with sex hormone deficiencies, adrenal cortical tumors and the genetic and endocrine factors in the growth and development of childhood and adolescence. This volume will be of exceptional value to the steroid chemist and to the experimental and clinical endocrinologist.

The Care and Management of Laboratory Animals: Handbook of the Universities Federation for Animal Welfare. With an Appendix on Statistical Analysis. Edited by Alastair N. Worden, M.A., B.Sc., M.R.C. V. S., Milford Professor and Director of Research in Animal Health, University College of Wales, Aberystwyth. With a foreword by Professor T. Dalling, M.A., M.R.C.V.S., F.R.S.E., Director, Veterinary Laboratory, Ministry of Agriculture and Fisheries, Weybridge, Surrey. Cloth. Price, \$3.50. Pp. 368, with 70 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

In addition to presenting in meticulous detail all necessary information regarding proper care of laboratory animals, this volume contains a general chapter, by Major C. W. Hume, M.C., B. Sc., on law and practice in relation to the rights of these important partners in medical research. The discussion contains historical notes and a presentation of basic principles that should be required reading for every laboratory worker, from director to bottle washer. Carrying the subtitle, "Handbook of the Universities Federation for Animal Welfare," the book contains contributions from numerous reliable sources. There is some lack of orderliness in the approach of the various chapters as a result, but this is unimportant. All chapters include details on stock accommodation and equipment, feeding, handling and marking, breeding, anesthesia and species diseases and their control. Sixty-three illustrations, including diagrams and photographs of pens, cages and tanks, add to the practical value of the discussion. There are details on a wide variety of laboratory animals in common use, including the ferret, various rat and mouse species, the vole and the rather recently introduced golden hamster. A special chapter is devoted to pests of the animal house and their control, and another contains notes on care of anthropoids, dogs and cats, horses, shrews, vampire bats, poultry, reptiles and marine forms. In an appendix is presented a comprehensive survey of the elements of statistical analysis by Major Hume, with special sections on biologic assay and planning. The entire section is replete with formulas, charts and tables. The book should provide much aid for laboratory workers everywhere.

When You Marry. By Evelyn Mills Duvall, Secretary, National Council on Family Relations, and Reuben Hill, Associate Professor of Sociology, Iowa State College, Ames, Iowa. Cloth. Price, \$3. Pp. 450, with illustrations. Association Press, 347 Madison Ave., New York 17, 1948.

One of the authors of this book is secretary of the National Council on Family Relations; the other is associate professor of sociology in Iowa State College. The preface states that "this book has been written to supply the kind of guidance that is sought and needed 'when you marry.'" The foreword emphasizes the functional approach to teaching marriage and family living, and explains at some length how this is accomplished. The foreword is written by Ernest W. Burgess, of the University of Chicago.

The book is organized into four parts, dealing respectively with "Anticipating Marriage," "What It Means to Be Married," "The Making of a Family" and "Family Life Yesterday, Today, and Tomorrow." On the jacket it is claimed for the book that it covers the gamut of personal relationships from first date to last baby. In general it may be said that this claim is fulfilled.

In part I are chapters dealing with what the partners bring to the marriage with respect to heredity, personality development and other qualities. The second chapter essentially deals with the question: "How do you know it's love?" Subsequent chapters deal with dating, courtship, the meaning of an engagement, who gets married and to whom, marriage

and the facts of life, and morality makes sense. With the aid of amusing cartoons and an informal style, these chapters make easy reading, and they present a sensible philosophy which is neither too radical nor so conservative that youthful readers will be repelled.

In part II are chapters for the information of those just married, including suggestions about the honeymoon and settling down, establishing housekeeping and the major accomplishments of the first year of marriage. Another chapter deals with common conflicts in marriage and some rather surprising but definitely sensible thoughts about productive versus destructive quarreling. Marriage counseling is advocated as a help in many instances. There is a good chapter on money in relation to marriage and one on crises in the family relationships, including financial crises, desertion, infidelity and death. This is logically followed by a chapter on divorce which is unavoidably controversial. Those who adhere to the traditional opposition to divorce which is inherent in the belief of a number of religious groups will condemn the book on the basis of this chapter, which frankly has as its keynote the headline of one of its subsections, "Divorce Not Something to Fear or Condemn." On the other hand, this very attitude may recommend the book to persons of views divergent from those previously mentioned. Immediately following the chapter on divorce is one on what holds a marriage together. Part III has to do with the making of a family, with chapters on where babies come from, illustrated by photographs of the Dickinson models, another chapter on getting ready to be parents, one on what it means to be parents, and one on family life and religious living. This chapter will please or displease readers according to their religious views. Part IV has to do with the orientation of the family in relation to the past, the present and the future.

Subject to the differences of opinion inherent in philosophic and religious points of view, this book can be recommended for physicians to suggest to their patients.

The Baby's First Two Years. By Richard M. Smith, A.B., M.D., Sc.D. Fifth edition. Cloth. Price, \$2.75. Pp. 181, with illustrations. Houghton Mifflin Co., 2 Park St., Boston 7, 1948.

The material has been rewritten completely in many sections of this book to conform with recent knowledge concerning the care of infants. It has been an authoritative book for mothers for the past twenty years or more. The volume is divided into three parts. Part I, "The Care and Feeding of Infants," includes not only the usual chapters, but also one each on "Growth and Development," "Habits and Training" and "Sickness." Part 2, on "Suggestions to Mothers," contains a valuable chapter on "How to Travel with a Baby" and another on "A Typical Day," which summarizes and coordinates much of Part 1. Part 3 concerns itself with "Recipes and Charts." There are 181 pages of easily readable type, an index and 15 photographs $\frac{1}{2}$ to 1 page in size illustrating such things as putting on a diaper and equipment for the bath. This edition is written in an easily understandable, matter of fact style. There is perhaps not as much space given to psychologic phases and discussions as in some other recent "Baby Care" books. Dr. Smith takes a middle of the road attitude regarding daily schedules. He believes that the pendulum may have swung too far in both directions at various times.

I Love My Doctor. By Evelyn Barkins. Cloth. Price, \$3. Pp. 238, with illustrations by Alfred S. Plane. Thomas Y. Crowell Co., 432 Fourth Ave., New York 16, 1948.

This author loves her doctor, but she does not seem to love the medical profession or the practice of medicine. In the early chapters the doctor is still finishing his internship and the author studying for her degree in law. The story deals with the setting up of an office, the buying of a car, waiting for practice to appear and other events. One is not sure at first whether the primary purpose is to write an experience book on early marriage or one on starting a medical practice. While the author loves her own doctor, she seems to think most other doctors stupid. She jeers at medical meetings in general, tries to keep her husband off hospital staff appointments because she considers them political, and derides the scientific councils of the American Medical Association, of

which, incidentally she does not trouble to ascertain the correct names. Just why a doctor's wife should consider it funny to belittle the profession to which her husband belongs is not clear. The preceding book by this author has had a wide sale, and is said to have been hilariously funny. This one is not.

Surgical Applied Anatomy. By Sir Frederick Treves, Bart. Eleventh edition revised by Lambert Rogers, M.Sc., F.R.C.S., F.R.C.S.E., Professor of Surgery, University of Wales. Fabrikhold. Price, \$6. Pp. 560, with 192 illustrations. Lea & Febiger, 600 S. Washington Sq., Philadelphia 6, 1947.

This little book, originally written sixty years ago, is probably the oldest textbook of surgical anatomy written in English to remain in current use. Despite its age and many revisions, it still fulfils Treves' conception of a "modern account of the application of anatomy to practice." It divides the body into six regions—head and neck, thorax, upper extremity, lower extremity, abdomen and pelvis, and spine and cord. Each is amply covered from the standpoint of general surgery as well as of the various surgical specialties. Many subjects, such as surgery of the blood vessels, which deals with ligations, abnormalities and collateral circulation, are omitted for the sake of brevity, "since these are fully treated in manuals of general anatomy." The work is easy to read. It is not abundantly illustrated, but the drawings present enhance the value of the text. The survival as well as the appeal of this book to the student, teacher and practitioner, particularly in England, is indicative of its usefulness.

Physical Treatment of Injuries of the Brain and Allied Nervous Disorders. By R. M. Hern, M.C.S.P., in Charge of Physiotherapy Dept., Military Hospital (Head Injuries), Oxford. With a foreword by Air Vice-Marshal Sir Charles P. Symonds, K.B.E., C.B., D.M. Cloth. Price, \$4. Pp. 96, with 34 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1947.

This short monograph presents in considerable detail a method of treatment of hemiplegia and other upper motor neuron disorders by means of active exercises. These include methods of teaching walking and rhythmic exercises for coordination with minimal apparatus. To develop functional ability of the upper extremities the most important equipment is three sizes of balls used in exercises and games. Other standard gymnasium equipment is also described and advocated. A few types of occupational therapy procedures are included. The complete problem of rehabilitation of these patients including social and economic adjustment is not fully covered. Physicians and technicians dealing with these problems will find practical information satisfactorily described and illustrated. It is recommended more as a reference textbook, as it does not completely cover the problems in this important field of physical rehabilitation.

Die Röntgendiagnostik der Wirbelsäule und ihre Grundlagen. Von Dr. med. Adolf Liechti, Professor für medizinische Radiologie, Direktor des Röntgeninstitutes der Universität Bern, Bern. Second edition revised by A. Eggli. Paper. Price, Dollar br. 13. Pp. 364, with 234 illustrations. Springer-Verlag OHG, Mölkerbastei 5, Vienna 1, 1948.

This book is written from the point of view of the radiologist. He describes the embryology of the vertebra and the disks, the various stresses and strains to which the back is subjected, and the physiology and static factors of the muscles of the back. He illustrates hemivertebra, butterfly vertebra, spina bifida, gorilla vertebrae and various anomalies and variations. Scheuermann's lesion, Calvé's lesion, and Cushing's lesion, arthritis of all types and infections, osteomyelitis and primary and secondary tumors are discussed. The bibliography, chiefly foreign, occupies 96 pages. This makes the book too heavy.

Control of Pain with Saddle Block and Higher Spinal Anesthesia. Edited by J. H. Walton, M.D., Cloth. Gratis to Physicians. Pp. 52, with illustrations by Frank H. Netter, M.D. Ciba Pharmaceutical Products, Inc., Summit, N. J., 1948.

This monograph describes the technics and gives other pertinent data on saddle block anesthesia (low spinal anesthesia limited more or less to anatomic parts that would be in contact with rider's saddle) and conventional spinal anesthesia for normal and operative obstetric deliveries. The only drug recommended is dibucaine hydrochloride. There are 12 excellent plates in color drawn by Frank H. Netter, M.D. The monograph will interest anesthetists and obstetricians.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LOSS OF HAIR PIGMENTATION

To the Editor:—What could be the cause of the loss of pigmentation of the eyelashes and eyebrow of the right side over a period of three to four months. This patient is 4 to 5 years of age and somewhat overweight. Present weight is 58½ pounds (26.5 Kg.). What is the possible etiology and treatment in this case?

Darrel L. Evans, M.D., Manhattan, Kan.

ANSWER.—Premature whitening of the eyelashes and eyebrows, not due to locally applied bleaching agents, has been described in association with a number of diseases and injuries. Alopecia areata and vitiligo frequently accompany the disorder, and it has been described as occurring in trigeminal neuralgia, nerve injuries, peripheral neuritis, severe emotional trauma, iridocyclitis, interstitial keratitis, sympathetic ophthalmia, and following painful ocular surgical operations. Theoretically, the loss of pigment is ascribed to rapid penetration of the hair by air, to inhibition of pigment formation in the cortical cells of hair-bearing skin, to a circulatory change causing disturbances in distribution of pigment, to anaphylactic phenomena and to congenital factors.

No treatment is indicated; the affected hairs usually regain their pigment in a few months. Occasionally removal of the white cilia is followed by a growth of normally pigmented hairs. A good review and bibliography of the subject is contained in Hague (Uveitis; Dysacusia; Alopecia; Poliosis and Vitiligo. *Arch. Ophthalm.* 31:520, 1944).

TETRACHLORETHYLENE

To the Editor:—Please discuss the toxic effects of perchlorethylene on the liver as compared with carbon tetrachloride and trichlorethylene. What other chemicals does a "silk spotter" come in contact with that might cause damage to the liver? Would it be advisable for a "silk spotter" using perchlorethylene and having evidence of Laennec's cirrhosis of the liver to return to his occupation?

Lieut. (ig) W. H. Sprunt, MC, Batavia, N. Y.

ANSWER.—Perchlorethylene (tetrachlorethylene) along with trichlorethylene is much less toxic than carbon tetrachloride. In part this is due to lower vapor pressure and in part to the fact that perchlorethylene in the body decomposes to less active constituents while carbon tetrachloride likely remains intact and at least in exhaled air appears as such. Moreover, perchlorethylene damages the liver to a lesser extent than carbon tetrachloride. Its chief point of action may be on the cardiovascular-renal system and on occasion may be associated with pulmonary edema.

The "silk spotter" in a dry cleaning establishment is the "fancy spotter" doing work more complicated than the "rough spotter." Fancy spotting, in addition to silks, extends to divers synthetic fabrics. The silk spotter's table is likely to present a large array of chemicals calling for skill and experience. Some chemicals highly suited to silk will dissolve the synthetics. This trade is highly individualistic. Every spotter is likely to have a few personal secret concoctions that make him superior to the ordinary spotter. Almost anything may appear on his bench. The number will include carbon tetrachloride, perchlorethylene, chloroform, benzene, naphtha fractions, phenols and creosols, hydrofluoric acid, acetic acid, ammonia water, carbon disulfide, various alcohols, and such.

Spotter's benches are practically never ventilated. They should be. Since as little as a spoonful of carbon tetrachloride may provoke disaster it may be believed that this and other practical exposures readily come about. However, the real problem is not what chemicals appear on the spotting bench but instead how extensive the exposure therefrom and what protection is provided. "Spotters" like galvanizers are prone to alcoholism, there possibly being some "stimulation" from the chemicals employed. Any persons with Laennec's cirrhosis probably may be more easily involved in further hepatic damage than a wholly normal person. It would appear that the more salutary answer may derive from properly ventilated work booths rather than from removing the spotter involved in some degrees of hepatic damage. Alcoholism should be discouraged. Particularly alcohol accelerates the action of carbon tetrachloride.

BARBITURATES

To the Editor:—What are the relative merits of pentobarbital sodium ("nembutal") and "seconal sodium" as compared with phenobarbital and the specific indications for and dosages of each of these drugs?

S.S. Lasky, M.D., Brooklyn, N. Y.

ANSWER.—Pentobarbital sodium ("nembutal") and "seconal sodium" belong to the group of barbiturates usually classified as "short acting," whereas phenobarbital belongs to the "long acting" group.

Pentobarbital and "seconal" may be used as hypnotics to induce sleep in nervous or excitable patients. The rapid destruction in the body generally assures that the depressant effects will have disappeared at the end of a normal period of sleep (eight hours), and hence the so-called "barbiturate hangover" is usually absent. The hypnotic dose of pentobarbital and "seconal" is about 0.1 Gm. Both drugs may be used for pre-anesthetic sedation, the dose being 0.1 to 0.2 Gm.

Phenobarbital, because of the presence of the phenyl group has a prolonged action and is used wherever prolonged sedation is required. Hence it is not useful for the treatment of insomnia or as preanesthetic medication. Phenobarbital is chiefly used as a sedative and anticonvulsant in the treatment of epilepsy and has also been proposed as a sedative in circulatory and cardiac disorders. The average dose is 0.1 Gm.; the dose varies from 15 mg. to 0.2 Gm.

JIUJITSU

To the Editor:—Would jiu-jitsu not represent an ideal sport for self defense and physical training avoiding the dangers and brutalizing effects of boxing?

Leopold J. Schwarz, M.D., Wildwood, N. J.

ANSWER.—Various sources classify the technics of judo or jiu-jitsu into three divisions or "arts" including throwing (nage-waza), holding down (kataame-waza) and striking (ate-waza).

While judo or jiu-jitsu means "gentle way" or "gentle art"—first giving way so as to gain eventual victory, its striking, kicking and choking aspects hardly fit the definition.

Among the approved methods of scoring a point and winning a bout are: throwing the opponent flat on his back, holding the opponent down for thirty seconds, choking the opponent until he becomes unconscious or signifies defeat, causing the opponent to give up through the application of torture holds, hitting the opponent in a vulnerable spot.

During the last war, the immediate enemy in the Pacific happened to be the chief exponents of the activity. Interest in judo or jiu-jitsu in this country naturally became intensified. It is doubtful whether the activity would normally fit into the sport mores of what is now a rather well established American pattern. Further, as a peacetime pursuit, it is difficult to reconcile such activity with the social aims of a democracy.

In time of war, when the individual becomes more or less expendable, the situation is altered. With life or death sometimes dependent on skills of self defense, in hand to hand combat any means to the end becomes acceptable. The technics of judo, however, cannot be mastered in a short training period. Japanese experts spend years learning its intricacies, advancing through several ranks before qualifying for the higher ratings. In this connection it is interesting to note that toward the end of World War II many of our leaders became convinced that the best means of self defense for American youth were to be found in the familiar rough and tumble tactics growing out of American sports, coupled with those disarming and offensive skills that could be taught in a relatively short period of time.

ERYTHROBLASTOSIS

To the Editor:—What is the relation of apparently a cured erythroblastosis fetalis to the subsequent development of spasticity in the child? Please give sources for further information.

Robert E. Heerens, M.D., Batavia, Ill.

ANSWER.—The relation of erythroblastosis fetalis to cerebral damage is obscure, but it is quite clear statistically that there is an extreme high incidence of infantile jaundice and blood incompatibility among children suffering from mental deficiency, athetosis, spasticity and other cerebral defects of early infancy. The subject has been considered in several recent publications, among which are the following:

Yannet, H., and Lieberman, R.: Central Nervous System Complications Associated with Kernicterus, *J.A.M.A.* 130:333-340 Feb. 9, 1946, Neurological Defects and the Rh Factor, *Internat. Med. Digest.* 48:55-58 (Jan.) 1946.

TRICHOMONAS VAGINALIS

To the Editor:—What is the latest information on treatment of *Trichomonas vaginalis* infection? I have 2 patients that I have been unable to relieve. We have used all standard treatments and searched for all points of infection and sources of reinfection.

Sam B. McFarland, M.D., Lebanon, Tenn.

ANSWER.—In nearly all cases of *Trichomonas vaginalis* infection, relief can be given the patient promptly by many forms of treatment. However, while it is easy to produce a temporary cure it is often difficult to give permanent relief. In refractory cases and in cases in which recurrences are frequent, a diligent search for a source of reinfection must be sought in the cervix, Skene's glands, the bladder and urethra, Bartholin's glands, the rectum and the husband's prepuce and prostate. Of course, if the trichomonads are found in any one of these organs, an effort should be made to get rid of the organisms.

Ray E. Trussell in an excellent book, "*Trichomonas Vaginalis and Trichomoniasis*," (Springfield, Ill., Charles C Thomas, Publisher, 1947) pointed out that failure to cure vaginal trichomoniasis is suggestive of resistant forms, but he also suggested that (1) rectal, urethral and glandular involvement were overlooked; (2) treatment was inadequate or inappropriate; (3) reinfection occurred, or (4) a drug-resistant strain developed.

Trussell stated: "The final word in the therapy of *trichomonas vaginitis* is far from having been written. At present the most commonly employed agents included aldarsone, carbarsone, acetarsone, silver picrate, floroquin, lactobacilli, and vioform. There is a current trend to the use of acid creams and jellies with or without the addition of protozoacides other than the acids. Good results have been achieved with most of these in the hands of careful investigators."

In a series of cases in which 98 per cent of the patients were cured, the treatment consisted of drying the vaginal tract and then applying by insufflation 2 to 4 Gm. of a powder containing 20 per cent by weight of finely pulverized mild silver protein ("argyrol"), 40 per cent of kaolin and 40 per cent of beta-lactose.

The patient was instructed to take a nightly douche, containing white vinegar (4 tablespoonfuls to 2 quarts of warm water) followed by insertion high into the vagina of a no. 12 gelatin capsule containing an additional 4 Gm. of the mild silver protein, kaolin and lactose powder. One week's supply of capsules was given, and the patient was asked to return at the end of that time, having taken the only douche (omitting medication) on the night preceding examination.

Patients were instructed to give careful attention to feminine hygiene to prevent reinfection from any of the possible sources. Treatment was not interrupted during the menstrual period.

The number of weeks of treatment given, in the absence of recurrence, was between three and four, and in the presence of one or at most two recurrences, between five and seven.

ENCEPHALOPATHY

To the Editor:—Are there publications on: (a) early differential diagnosis by means of the prothrombin time of embolic, thrombotic or hemorrhagic encephalopathy; (b) therapy of thrombotic encephalopathy by means of anticoagulants such as heparin and "dicumarol"; (c) the relative merit of the anticoagulant method in thrombotic encephalopathy as compared to the method procainization of the ganglion stellatum as described recently by Geza de Takats in *The Journal* (136: 659 [March 6] 1948)?

Wladimir G. Eliasberg, M.D., New York.

ANSWER.—The first question is based on the assumption that the prothrombin level of the blood is a measure of the patient's clotting tendency. It is true that the hemorrhagic tendency of jaundice and the state of the blood after "dicumarol" therapy are accompanied by a diminished level of prothrombin in the blood. It has also been observed that increased prothrombin levels, a state of hyperprothrombinemia, can be found in persons shortly after operation or after childbirth. This however, is only true when prothrombin is measured in diluted plasma, and Quick has always criticized these methods as not determining true plasma-prothrombin levels and thus being artefacts.

But even if an increased prothrombin level were a consistent finding in recent intravascular clotting, a diagnosis between cerebral embolus, thrombosis or hemorrhage would not be possible, since all three of these vascular accidents raise the clotting tendency. Thrombosis increases the clotting tendency; embolus of course is a thrombus, broken loose, and hemorrhage is well known to shorten coagulation time; added to this is the state of dehydration in which most of these patients are found within a few hours, and this itself increases the tendency to clotting. The correspondent does not know of any published article which

tries to differentiate the three forms of cerebrovascular accident by determinations of prothrombin levels, but on the basis of our present knowledge useful findings cannot be expected.

Question (b) refers to the use of anticoagulants in cerebral thrombosis. This is practiced on some services throughout the country but requires the elimination of cerebral hemorrhage from the group under treatment; since anticoagulant therapy per se has been known to produce cerebral hemorrhage, caution is indicated; heparin had better not be employed, and "dicumarol" given in conjunction with 200 mg. of rutin a day to counteract capillary fragility which may develop with the use of "dicumarol." The prothrombin level should not be allowed to drop below 30 per cent of normal in this group of patients.

(c) The relative merits of the anticoagulant therapy as compared to the sympathetic block in cases of cerebral thrombosis have not been described. Judging from results obtained in vascular thrombosis of the extremities, both methods can be used simultaneously, since they complement each other and act by different mechanisms; anticoagulants prevent propagation of the thrombus, and sympathetic block relieves the stasis and edema around the cerebral infarct. To answer summarily the three questions of the inquiry: there are no publications available at present. Further information may be obtained by consulting the following authors:

Quick, A. J.: *The Hemorrhagic Diseases and the Physiology of Hemostasis*, Springfield, Ill., Charles C Thomas, Publisher, 1942.

Bramble, L. E., and Loher, E. F.: *Proc. Soc. Exper. Biol. & Med.* 53: 218, 1943.

de Takats, G.: *Heparin Tolerance: A Test of the Clotting Mechanism*, Surg., Gynec. & Obst. 77: 31 (July) 1943.

Hagedorn, A. B., and Barker, N. W.: *Coagulation Time of Blood Heparinized in Vitro: Correlation of Results with Those of the Heparin Tolerance Test*, J. Lab. & Clin. Med. 32: 1087 (Sept.) 1947.

MALE STERILITY

To the Editor:—What treatment is indicated for a man aged 30 years, otherwise in good health, who is sterile? A fresh specimen of semen shows a large number of well developed spermatozoa, except that they are all immotile.

Robert C. Tavlin, M.D., Mooreland, Okla.

To the Editor:—Is there a hormone that will reactivate spermatozoa that have been in a semidormant state for some time? The patient is 40 years old.

A. E. Goebel, M.D., Montrose, Ill.

ANSWER.—In freshly ejaculated semen the spermatozoa nearly always possess some degree of motility. When examination shows poor motility, or none, the reason is usually a technical fault in collecting or handling the specimen. Materials used in the manufacture of ordinary condoms may kill even the liveliest cells within half an hour. Heat at first stimulates the activity of the spermatozoa, with the end result that their inherent vitality is more quickly exhausted. Cold can immobilize them, thus producing apparent necrostermia though the cells are not necessarily dead.

When initial motility is subnormal or, as happens in rare cases, completely lacking, several possible causes must be considered. Poor spermatogenesis may yield cells so immature or morphologically imperfect that they are incapable of any activity. If the male duct system and its accessory glands do not function properly, spermatozoa may fail to "ripen" in the epididymides or to receive their normal physiologic stimulation from the prostatic secretions. Chronic infection or congestion of the prostate and vesicles may produce such viscosity of the seminal fluid that motility is mechanically impeded.

The first step in differential diagnosis should be the examination of a stained smear of semen with regard to the incidence of poor morphology. Faulty functioning of the epididymides and accessory glands may be indicated by small volume and increased viscosity of the ejaculate, and is further suggested if hormone assays show hypogonadism. Prostatovesiculitis can be diagnosed by the usual methods of studying the expressed secretions.

As a general basis for treatment the patient's health and hygiene receive all necessary attention. If his basal metabolic rate is below plus 10, it should be raised and maintained at that level by the carefully regulated administration of thyroid. More specific therapy will depend on the faults identified in his genital tract. Poor spermatogenesis may respond to gonadotropins, though the results in most cases are disappointing. Small doses of testosterone sometimes improve the functioning of the duct system and its glands; large doses are inadvisable, since they tend to depress the gonadotropic activity of the anterior pituitary. Chronic prostatovesiculitis should be treated by the accepted urologic techniques.

PITUITARY DEFICIENCY

To the Editor:—A white woman aged 30 has had her condition diagnosed by competent specialists as a pituitary deficiency. Her major complaints during the period of examination and treatment were facial hirsutism and an abnormally large distribution of fat in the legs, thighs and hips. She is soon to be married. What are the possibilities of her children inheriting this tendency?

M.D., Arkansas.

ANSWER.—It is impossible to make a diagnosis on the basis of the information provided; it might be impossible with all the information. If this woman 30 years of age is simply fat and hairy and if she has been menstruating, in all probability there is no reason to incriminate the pituitary gland. Most such girls and women respond satisfactorily to a weight-reduction program and local attention for the hirsutism. If this patient is really suffering from a pituitary deficiency, she probably could not become pregnant. In any event, there is no evidence that disturbances of the pituitary gland are hereditary. Every physician has observed obesity and hirsutism as parts of racial and family patterns.

HYPEROSMIA

To the Editor:—What is the best method of dulling the sense of smell? I have a maternity patient with an unusually keen sense of smell, which causes much nausea. If her olfactory organs could be impeded, she would improve.

Eugene Smith, M.D., Waterloo, Ia.

ANSWER.—Although it is a variable entity hyperosmia may be a symptom of hysteria or a psychosis. It may also be an indication of local functional disturbance in the olfactory lobe. The perception of odors is occasionally exaggerated during the early stages of pregnancy. Since nasal pathologic conditions seldom cause hyperosmia, attempts to dull the sense of smell through local medicaments would be inadvisable. During pregnancy psychogenic factors are likely to be strong. Reassuring the patient that she is normal and that the sense of smell will improve are of prime importance. She may be advised to carry on her person a bottle of agreeable perfume to counteract disagreeable odors.

DIABETES INSIPIDUS

To the Editor:—Please give information on use of posterior pituitary extract orally to control the symptoms of diabetes insipidus. Is it as efficacious as when used parenterally?

LaMar J. Hankamp, M.D., Delton, Mich.

ANSWER.—Posterior lobe pituitary extract is not effective when given by mouth. It is most effective when given parenterally, and relief of symptoms of diabetes insipidus is obtained in most cases when posterior pituitary or, better still, the antidiuretic principle known as "pitressin" is given subcutaneously. For long-continued effect the intramuscular administration of "pitressin tannate in oil" is desirable.

Good absorption is obtained usually through the nasal mucosa. Many patients with diabetes insipidus respond excellently to the insufflation of posterior lobe pituitary powder, and this, incidentally, is the least expensive form of treatment. Somewhat less effective when applied to the nasal mucosa are ointments and solutions containing pituitary extract.

TRIETHYLENE GLYCOL

To the Editor:—Please furnish information regarding use of triethylene glycol as a preventive of colds and virus infections.

W.B. Inman, M.D., Sosa, Miss.

ANSWER.—The use of triethylene glycol as a preventive for colds and virus infections is still highly experimental. We lack satisfactory evidence that under the conditions of use which would be practicable in a home, office or factory any significant diminution in the incidence of viral infections can be obtained.

Triethylene glycol is manufactured by the Carbon and Carbide Chemicals Corporation and by the Dow Chemical Company.

LIPIODOL

To the Editor:—Is there a substitute for iodized oil ("lipiodol") with which to make bronchogram studies on a patient who has a marked sensitivity to iodine? If so, where can it be procured?

John W. Stacey, M.D., Tucson, Ariz.

ANSWER.—Unfortunately, there is no satisfactory substitute for iodized oil in bronchography. Experimentally, compounds containing bromine have been tried, but they are too irritating and fail to cast a satisfactory shadow.

COBRA VENOM

To the Editor:—What is the consensus relative to the use of "cobra venom" in intractable pain in cancer? A patient is using more narcotics with less relief. Prognosis is that she will live for another year or more.

G. N. Green, M.D., Elgin, Ill.

ANSWER.—The pharmacology and the therapeutic value of preparations of cobra venom (*naja*) have been described in the following references.

The consensus is that cobra venom is useful in relieving severe chronic and prolonged pain, especially in advanced cases of cancer and also of neuritis from other cause. Toxicity of such preparations is not great, and the chief point to be kept in mind is that efficient dosage must be determined for each patient separately. The principal advantage of cobra venom therapy is that it is not depressing for the higher centers of the brain and that it can also be substituted gradually for the opium narcotics in cases of narcotic addiction.

LOW CHOLESTEROL DIETS

To the Editor:—What is the present opinion regarding low cholesterol diets in patients who have had coronary thrombosis? Please give references to the cholesterol value of foods.

M.D., Tennessee.

ANSWER.—The value of low cholesterol diets in coronary thrombosis is not clearly established. In some instances such a diet reduces an abnormally high serum cholesterol to a normal level; in others it has little or no effect. Factors other than the cholesterol content of the diet may be important in maintaining a high serum cholesterol level; namely, the level of metabolism, the state of hepatic function and the type of food which the body converts into cholesterol. Little is known about what "precursors" are important in human nutrition.

A complete table of cholesterol value of foods is given by Okey, R.: *Cholesterol Content of Foods, J. Am. Diet. A.* 21: 341 (June) 1945.

PENICILLIN IN OIL IN PEDIATRICS

To the Editor:—Is the adult dose of 300,000 units of penicillin in oil harmful to an infant or young child?

L. Gruenewald, M.D., Sheboygan, Wis.

ANSWER.—The dosage of 300,000 units of penicillin in oil will not cause any damage to an infant or a young child.

DIPHTHERIA VIRULENCE

To the Editor:—In *The Journal* on page 955 of the issue of April 3, 1948, I note an affirmative answer to an inquiry concerning the virulence of diphtheria bacilli, "Can the same organism found to be nontoxic by guinea pig inoculation on one occasion be capable of changing its virulence after repeated cultures or after repeated animal or human passage?"

So far as I know there is no sound basis for this answer. All evidence is to the contrary, i.e., that diphtheria bacilli whether toxigenic or nontoxigenic remain unchanged in regard to these properties. Possibly the only suggestive results were obtained by Roux, who thought that he had altered the virulence of diphtheria bacilli, but his controls were not clear and no other conclusive experiment on these lines has ever confirmed him. One or two reports of alterations in virulence of toxigenic diphtheria bacilli include alteration in morphology and fermentative characters so that the organism of changed virulence is no longer recognizable as a diphtheria bacillus and may actually represent contamination.

Martin Frohisher Jr., Sc.D., Baltimore.

CONGENITAL CATARACTS

To the Editor:—I read with some interest your reply to "M.D." questioning the treatment of congenital cataracts (*The Journal*, volume 136, page 809).

Perhaps in the broader sense your reply is quite correct. It is, however, important that the child in question should develop fixation. The macula, as is well known, is not developed at birth, and subsequent growth appears dependent on the stimulus of surrounding objects. This, of course, is not likely when congenital cataracts exist—provided they are total. The prognosis when fixation nystagmus has developed is not good.

Nor would I be too optimistic about the late prognosis in the patients. They appear notoriously susceptible to major complications following intraocular surgery. Detachment of the retina and late secondary glaucoma are common causes for loss of vision in early adult life.

Dr. Arnold Knapp (*Arch. Ophth.* 32: 403-406 [Nov.] 1944) discussed this matter thoroughly some years ago.

Alfred A. Stonehill, M.D., New York.

RHEUMATOID ARTHRITIS

The Importance of a Comprehensive Approach in Treatment

Chairman's Address

WALTER BAUER
Boston

The cause of rheumatoid arthritis remains unknown. Although many theories have been proposed, no one of them has been generally accepted. To date, there is no method of treatment for rheumatoid arthritis which can be considered "specific"—a term which implies rapid and complete reversal of subjective and objective manifestations of the disease, whether localized to the skeletal system or other parts of the body. Until this long-awaited discovery is at hand, the treatment of rheumatoid arthritis is necessarily confined to those measures believed to be beneficial but not necessarily of proved value. It is the purpose of this report to review briefly the nature of the disease, to outline the minimal requirements for the assessment of newer methods of treatment and to stress the importance of a comprehensive approach in the treatment of patients with this disease.

NATURE OF THE DISEASE

Rheumatoid arthritis presents a variety of clinical forms and pursues no single pattern of development. It must be regarded as a distinct disease entity that can readily be recognized. Space does not permit more than a listing of the outstanding features that distinguish rheumatoid arthritis from other forms of joint disease. It is essential to realize that one is dealing with a generalized disease with well marked constitutional manifestations that are not merely secondary to the articular lesions. Female subjects are more commonly affected than male, except in cases in which the spine is involved. The onset is not limited to any age group and may occur from infancy to senility. The constitutional symptoms often precede the appearance of objective joint signs, and it is thus possible to surmise the diagnosis in what may be termed a prodromal stage. Precipitating factors, such as physical or emotional strain, infection and accidental or operative trauma, often appear to play a role both in the initiation of the prodromal symptoms and in the production of articular manifestations of the disease. The type of onset ranges from the insidious to the explosive, with endless variations between. In many

patients the initial complaints are fatigue, exhaustion, lassitude, loss of weight and symptoms referable to the nervous system and the vasomotor apparatus. In cases of severe disease these symptoms may be profound. Both large and small joints are affected, at first perhaps in a migratory fashion but later with unrelenting persistence. Examination of the joints reveals no early observations that are specifically different from those of other forms of arthritis. The signs of inflammation, usually mild and often accompanied with effusion, almost always precede the development of limitation of motion and deformity. More important is the symmetric polyarticular distribution of the arthritis, although involvement of one or a few joints is not uncommon in the early stages. Muscular weakness and atrophy are prominent, and inflammation of muscles and extra-articular fibrous tissue is almost invariably present. Subcutaneous nodules form a characteristic part of the clinical picture in about 20 per cent of the cases. Involvement of other organs of the body is evidenced in certain cases by cold, clammy hands and feet, atrophy and pigmentation of the skin, lymphadenopathy and splenomegaly, pericarditis and pleuritis and ocular changes including iritis, uveitis, scleritis and scleromalacia perforans. The course of the disease is all too often one of steady or intermittent progression, although complete or nearly complete remissions are not unusual at first, and certain patients recover without significant residual disability.

The laboratory studies, although not of diagnostic help, may aid in the determination of the severity of the disease. The sedimentation rate of the red cells and the Schilling or filament-nonfilament count are useful in following the course of the disease, but only occasionally in differential diagnosis. In approximately 50 per cent of the cases, the serum of patients with rheumatoid arthritis agglutinates strains of hemolytic streptococci of Lancefield group A in a characteristic manner. In such cases, a positive reaction to a test is of value in distinguishing rheumatoid arthritis from other forms of arthritis in which agglutinations are encountered only rarely. Unfortunately, the reaction to the test is rarely positive in patients having the disease less than one year. The antistreptolysin and antifibrinolysin titers in rheumatoid-arthritis serums are not characteristic, whereas rheumatic fever serums usually show elevated values. Biopsy of subcutaneous nodules is frequently of aid in differentiating the former disease from the latter. Examination of synovial fluid is helpful in ruling out traumatic arthritis, degenerative joint disease and the specific infectious arthritides. Hypochromic anemia is also observed in cases of severe disease. The white blood cell count varies considerably. In most cases, it is within normal limits or only slightly elevated. In the acute and active stages, counts of 12,000 to 20,000, occasionally higher,

The arthritis studies in this clinic were made possible by a grant from the Commonwealth Fund, New York.

This is a publication of the Robert W. Lovett Memorial Foundation for the study of crippling diseases, Harvard Medical School.

Read before the Section on Experimental Medicine at the Ninety-Seventh Annual Session of the American Medical Association, Chicago, June 24, 1948.

From the Medical Clinic, Massachusetts General Hospital, the Department of Medicine, Harvard Medical School, and the Massachusetts Department of Public Health.

may be observed, whereas in cases of long-standing chronic disease definite leukopenia may develop. Roentgenograms in joint disease must always be interpreted in the light of the duration, severity and articular distribution. With the aid of such facts, accurate roentgenologic diagnosis of rheumatoid arthritis is usually possible. The characteristic features include soft tissue swelling, effusion, systemic decalcification of bones, loss of bony substance in "punched-out" areas, narrowing or even obliteration of the joint space, marginal erosion and, finally, subluxation and gross bony destruction. No single feature mentioned constitutes a diagnostic criterion, and it has been truly said that the picture differs from that of specific infectious arthritis largely in speed of progression.

Postmortem examinations confirm the systemic nature of rheumatoid arthritis, inflammatory lesions being demonstrable in the skin, subcutaneous tissue, muscles, peripheral nerves, eyes and serous membranes, as well as the articular tissues. Such widespread involvement of nonarticular systems serves to stress the importance of a comprehensive approach in the treatment of patients with this disease.

ASSESSMENT OF NEWER METHODS OF TREATMENT

Patients with chronic diseases of unknown cause are frequently subjected to various therapeutic procedures that are of questionable merit and are usually based on conjecture. Such supposedly curative and ameliorative measures are regularly administered to patients with chronic rheumatoid arthritis, often at considerable expense, not infrequently with resulting complications, occasionally even death, and generally without material benefit to the patient. This state of affairs is due in part to the fact that patients with chronic diseases often demand treatment. They are ever hopeful that each new form of treatment prescribed will be as specifically curative as the advertisements claim. There are, however, other causes for the continued prescribing of many useless antirheumatic remedies. The premature publication of poorly controlled studies acclaiming great therapeutic benefits and voluminous medical advertising constantly confront the busy practitioner of medicine. He has neither the time nor the facilities to investigate adequately the claims made. Except for the reports of the Council on Pharmacy and Chemistry of the American Medical Association, its "Queries and Minor Notes" columns and the all too infrequent publications concerning the repudiation of previously published premature claims, the busy physician has no way to determine the respective merits of these therapeutic procedures.

In a chronic disease of unknown cause, such as rheumatoid arthritis, characterized by unpredictable spontaneous remissions and exacerbations, it is extremely difficult to evaluate the results of treatment with any degree of certainty unless the studies are rigidly controlled. Because of the decided variations in the course of the disease from case to case, each patient must be made to serve as his own control. If studies pertaining to the evaluation of therapeutic procedures are not conducted in this manner, one is likely to conclude that the improvement observed is the result of treatment, whereas it may actually represent the natural variation in the course of the disease. Such a controlled study can be made only by choosing patients whose clinical course and variations in sedimentation rate have been known for months or years prior to the institution of a new form of treatment. An adequate follow-up period is most essential, so that one

can decide as to the permanency of any improvement noted during the period of treatment. In addition to these precautions, it is extremely important that the patient be kept on the same basic regimen before, during and after the administration of the treatment being evaluated. Every available means should be employed in evaluating clinical improvement. One should record separately the subjective, objective and laboratory evidence of improvement, the final results being based on all three. In addition, one must judge the total severity of the disease. This is done by taking into consideration the degree of constitutional symptoms and signs, the speed of progression of the disease, the amount of disability, the extent of the involvement and the activity of the process. This method of recording enables one to establish more accurately what, if any, psychic effect must be taken into account in the final summation. In all fairness to the type of treatment being studied, only patients whose disease state is active and still reversible should be selected. That the activity of the disease process is reversible is shown both by spontaneous remissions and by those encountered in pregnancy and intercurrent jaundice. One must also realize that in the early and atypical cases there are more likely to be remissions than in the more typical cases which have been more or less stationary for a long time. If the administration of a given form of treatment should result regularly in improvement in this latter group, one might have reason to suspect that one is dealing with a specific form of treatment.

The early enthusiasm for each procedure is sooner or later dampened by the publication of critical well controlled studies, of the type outlined, with essentially negative results.¹ The exception is gold therapy, introduced nearly twenty years ago, although its acclaimed specificity has occasionally been challenged in recent years. Studying the efficacy of gold therapy in the manner described reveals that it cannot be regarded as a specific and constantly effective treatment for rheumatoid arthritis.² It is more difficult to state whether gold is of some benefit to the patient with rheumatoid arthritis and whether its use is therefore justified in a patient failing to respond to conservative measures. Two control studies apparently demonstrate an additive therapeutic effect on the part of gold during relatively brief periods of observation.³ Otherwise, the results obtained with gold may be approximated with those in patients given general conservative treatment. A careful follow-up study of patients improving during gold therapy reveals a high percentage of relapses, so that the net gain is slight. There is even an indication that the natural fluctuant course of the disease is largely responsible for the results reported in such cases. The burden of proof is still on the proponents of gold therapy to demonstrate by adequately controlled studies with a follow-up of three to five years that a significant effect is exerted on the course of rheumatoid arthritis by the administration of gold salts.

Gold therapy, like certain other antirheumatic drugs, is not without danger. The toxic manifestations are

unpredictable, unpreventable and, at times, irremediable. If the specificity of gold were established, this risk would be justifiable in a disease that bears the implications of lasting invalidism. With the case as yet unproved for its place as a palliative or adjuvant remedy in rheumatoid arthritis, the hazard of this form of treatment should furnish the decisive argument against its general use.

Dependence on any one therapeutic agent in the treatment of rheumatoid arthritis, unless it has a degree of specificity comparable to that of the sulfonamide drugs and penicillin in lobar pneumonia, deprives the patient of the benefit of constitutional treatment, physical therapy, orthopedic measures and other indicated therapeutic procedures.

IMPORTANCE OF A COMPREHENSIVE APPROACH

It is obviously impossible to select a true control series of untreated patients with rheumatoid arthritis. Nearly every patient with the disease in a recognizable form has received some form of treatment whether advised by his physician or someone else. Therefore, the advocates of a conservative therapeutic regimen, consisting largely of bed rest, psychotherapy, adequate analgesia, exercises to improve or maintain muscle and joint function, application of heat to actively involved joints, proper support for joints to allow reduction of muscle spasm and pain, the prevention and correction of deformities and an adequate diet, with supplementary vitamins when indicated and iron and transfusions when necessary,⁴ cannot prove that it alters the natural course of rheumatoid arthritis. Two hundred and fifty unselected patients with the disease who received this type of treatment were observed for an average period of ten years.⁵ Of this series, 23, or 9.2 per cent, were reported as five-year "cures" ("remissions" or "arrests")—a slightly higher figure than the 6.3 per cent recently reported for 142 patients given gold therapy.⁶

The systemic nature of the disease indicates that measures to increase the patient's resistance and place him in the best general health, in addition to proper handling of the inflamed articulations to promote healing and to preserve function, are in order. This is no easy task. It requires a full appreciation of the nature of the disease, the personality of the person afflicted and the importance of detailed management, as well as an abundance of patience, equanimity, ingenuity and resourcefulness on the part of the physician. Failure to approach the problem in this manner is frequently the cause of considerable frustration on the part of the physician treating patients with rheumatoid arthritis. If this reaction is not recognized, it may unconsciously impel the physician to resort to an endless number of therapeutic agents until such time as the patient wanders off to another physician, the use of patent remedies or quacks. Resort to methods of doubtful value may at times be necessary to hold the patient to the pursuit of a few simple measures of proved worth. In such instances, the physician should admit compromise with his intellectual honesty and admit that by doing so, he hopes to tide the patient over a discouraging period when the disease seems to be at a standstill or progressing in spite of all efforts. The possibility of a remission when things look darkest should never be

lost sight of. The startling freedom from symptoms gained from intercurrent hepatic jaundice or pregnancy points out that the process is not irreversible and that the long-awaited specific method of treatment may yet come to light.

Once the diagnosis has been made, the patient should know what is ahead of him and should be informed that there is no easy and rapid road toward arrest of the disease. He should also be made acquainted with the natural course of rheumatoid arthritis, so that he will not relax his precautions as a result of a remission or become overly depressed from an exacerbation.

The proper treatment of rheumatoid arthritis necessitates consideration of the patient as a human being. Attention must be given, not only to the many psychogenic factors that played a role in the precipitation and the progression of the arthritis, but also the various problems produced by the disease. There must be a realization that whatever emotional instability previously existed is increased by the illness. The effect of the financial load caused by the sickness and of the disruption of activity and of plans must be handled. At all times an attempt must be made to understand what the patient thinks about the disease, to be aware of and lessen his fear of it and to increase his insight into the effect of psychogenic factors on the course of the disease.

CONCLUSION

The treatment of patients with rheumatoid arthritis requires an understanding of the systemic nature of the disease, its many clinical manifestations, its varied clinical course and the persons afflicted. Until the advent of a specific therapeutic agent, treatment of this disease necessitates a comprehensive approach of the type briefly described.

RENAL PTOSIS AND ITS TREATMENT

WILLIAM F. BRAASCH, M.D.

LAURENCE F. GREENE, M.D.

and

RUY GOYANNA, M.D.

Rochester, Minn.

A listless meeting of urologists can be suddenly animated by the simple word "nephropexy." This usually will bring forth varying shades of opinion, many of which are extreme. The proponents of the operation will cite figures to show that the percentage of patients cured by this operation is as high as, or indeed higher than, that following most surgical procedures. In their opinion, the poor results from nephropexy result from improper selection of patients or poor surgical technic. The opponents of the operation are equally convinced that nephropexy results in only a small percentage of cures and that the failures are an inherent property of an ill conceived operation.

The urologic literature contains numerous reports which are enthusiastic about the brilliant results achieved by nephropexy. It will suffice to refer to but two of these reports. Mathé,¹ employing a technic for nephropexy which he devised in 139 cases, was able to cure or relieve 98.7 per cent of the patients. Post-operative pyelographic studies carried out in 71 cases revealed successful fixation of the kidney in 100 per

instances, denervation of the renal pedicle was performed simultaneously with nephropexy. The value of this procedure could not be determined, but since 3 of the patients in whom denervation was performed failed to get any relief of symptoms and since our experience with this operation in other types of cases has not been particularly reassuring, it would seem questionable whether it could be as important as some surgeons seem to think.

Nephropexy was performed in numerous other instances, either secondary to, or in conjunction with, other surgical procedures about the kidney. These cases were not included in the report, inasmuch as more than one surgical procedure was carried out and the value of nephropexy alone could not be determined. Nephropexy was performed more or less as a routine procedure after plastic repair for obstruction at or near the ureteropelvic juncture. It also was performed in many instances secondary to pelvolithotomy, to division of obstructing anomalous renal vessels or tissue bands and to renal malposition. These cases are not included in this report, although it cannot be denied that in some cases nephroptosis may have been an etiologic factor.

Results of Nephropexy.—Of the 21 patients who underwent nephropexy, 11 experienced more or less subjective relief from their symptoms; 10 patients were not subjectively benefited by the operation. Of the 11 patients with favorable results, only 3 had complete and permanent relief. In the other 8 cases the original pain was largely relieved, but other symptoms continued. A correlation could not be found between the degree of ptosis and the subjective results of nephropexy. It was noted that the incidence of pyelectasis or delay in emptying time was somewhat greater in the group of patients who received good subjective results.

It is difficult to explain the difference between our postoperative results—more than 50 per cent failure—and those achieved by urologists previously cited. It certainly was not due to failure of surgical technic, since the preoperative degree of ptosis was found to exist in only 1 of our patients examined after operation. It is possible that some of the uniformly good results claimed by some urologists were based on postoperative improvement reported within a few months after nephropexy. Several of our patients who reported no relief said they were much improved during a period of six months to a year after operation, but later symptoms similar to the previous ones returned. In 2 of our unimproved patients subsequent extrarenal complications developed to explain their pain. In 1 of these 2 patients acute disease of the gallbladder developed a year later, and cholecystectomy relieved the patient of her former symptoms. At the time of her clinical examination at the clinic the cholecystogram revealed no abnormality. The other of the 2 patients died a year later, and autopsy revealed a diffuse carcinoma involving the head of the pancreas, the liver and the gallbladder. These lesions were missed completely in spite of a careful clinical examination. Another patient without relief after nephropexy underwent nephrectomy elsewhere about two years later. Subsequently she reported that she had the same symptoms as before. It is evident that her symptoms, which we thought were typical of renal origin, had nothing to do with the kidney.

It is possible that we are somewhat pessimistic as to the results from nephropexy because of the many patients observed at the clinic who had had this operation performed elsewhere. Most of these patients came

with symptoms similar to those that existed prior to operation, in spite of the fact that the kidney was successfully anchored. Many of these patients had experienced temporary relief of symptoms after nephropexy, and then either the former symptoms returned or other complaints developed. To complicate the situation, in several patients who had been subjected to nephropexy elsewhere with relief of so-called renal symptoms, our urographic studies showed that the kidney which had been operated on had fallen to its preoperative low position. In another patient a right nephropexy had been performed elsewhere with relief of symptoms, but pyelograms and delayed urograms showed evidence of retention in both renal pelves. From this it was evident that atonic renal retention could be present without actual obstruction and without causing any symptoms. It is not unusual for patients who have been subjected to nephropexy to say that their symptoms have switched to the other kidney, in spite of the fact that the other kidney may be normal in position and function.

Many patients said that they had undergone elsewhere several operations prior to nephropexy, without relief of symptoms. Certainly one should hesitate before advising nephropexy on a patient who has already had cholecystectomy, appendectomy and possibly hysterectomy.

It is surprising how many patients with renal ptosis were benefited by means of palliative and corrective measures. Although renal pads, corsets or other types of abdominal support may not keep the kidney in place, yet many of these patients stated that such support gave them much relief. The relief can be explained either on psychologic grounds, on the basis of counterirritation or on the grounds that lumbosacral pain often is helped by some form of back support. Other measures, such as increased and nourishing diet, reduction in work and periods of rest and recreation, were of definite help in some cases, particularly if a gain in weight was effected. Psychosomatic treatment has benefited many and, if skillfully employed, may be the key to recovery. Many patients were included in this list who were in the menopause and who stated that their improvement became permanent after this period had been passed.

According to these observations, it would be no exaggeration to say that the problem of nephroptosis is not a simple one. It is evident that any one who advises nephropexy without careful and thorough consideration of all the factors involved and without giving the patient the benefit of other methods of treatment is doing that patient an injustice. The number of patients with nephroptosis who present clinical data which clearly indicate nephropexy is exceedingly small. These data should include not only intermittent pain with definite renal radiation, but also urographic evidence of borderline pyelectasis and delayed renal drainage. Even with this careful selection, no assurance of permanent relief of symptoms after nephropexy can be made. The fact that a few carefully selected patients have been benefited may justify the operation in occasional cases.

SUMMARY AND CONCLUSIONS

Nephroptosis occurs most frequently in thin, underweight women and most commonly affects the right kidney. Nephroptosis is not necessarily an abnormal condition, since it is present in a large number of cases, causing no symptoms or evidence of renal pathology.

The subjective symptoms accompanying renal ptosis are so variable and ill defined that they offer an uncertain guide in determining whether renal ptosis is an

etiologic factor. No correlation could be found between the varying grades of ptosis and the symptoms which might possibly be related to the kidney. Borderline pyelectasis, the so-called flabby pelvis, is often observed to be associated with renal ptosis.

Delayed renal drainage may be demonstrated in many cases by the delayed urogram. No correlation could be found in our series of patients between the varying degrees of ptosis and the presence or absence of pyelectasis or delay in emptying time.

Most patients with nephroptosis will be benefited by nonoperative measures.

Even in cases in which the symptoms point directly toward a renal origin, urographic data, such as evidence of a borderline pyelectasis or delayed drainage, should be required before nephropexy is considered.

Although evidence of delayed renal drainage, such as borderline pyelectasis and retained medium as observed in the delayed urogram, does not necessarily indicate obstruction, yet nephropexy is advisable only when such evidence is present, combined with symptoms of definite renal origin.

The fact that the symptoms were relieved in less than 50 per cent of our patients subjected to nephropexy after careful selection would, in itself, make one hesitate before advising this operation. A conservative attitude is substantiated by the fact that many patients observed at the clinic had previously undergone nephropexy elsewhere without relief of symptoms.

SURGICAL AND ROENTGENOLOGIC ASPECTS OF DUODENAL DIVERTICULA

JAMES G. CONTI JR., M.D.

THOMAS P. FOLTZ, M.D.

and

G. ARNOLD STEVENS, M.D.

Beverly Hills, Calif.

Much has been written concerning the frequency of occurrence of duodenal diverticula.¹ Too little stress, however, has been placed on the fact that in certain cases these diverticula cause symptoms which may be cured by surgical intervention. We agree that the majority of these lesions are innocuous and asymptomatic, but, on the other hand, we concur with Alesen² that symptoms do occur with sufficient frequency to cause the clinician and surgeon to keep this entity in mind.

We report 3 cases in which symptoms were eliminated by resection of the diverticula. One of the cases was of unusual interest, because the diverticulum contained an active ulcer in its base and because it occurred in the third portion of the duodenum. No such case to our knowledge has been reported. Most duodenal diverticula are situated adjacent to the ducts of Wirsung or Santorini, in the second portion of the duodenum.

ROENTGENOLOGIC ASPECTS

The manifestations of a diverticulum of the duodenum are essentially the same as those of a diverticu-

lum occurring elsewhere in the alimentary tract.³ The main characteristics are those of an outpouching, usually from the mesial wall of the second portion of the duodenum, connecting to the small intestine by means of a stalk. A single sac is usually present, but multiple outpouchings may occur.⁴ The diverticulum varies in size from several millimeters to 7 or 8 cm. As a general rule it is easily movable under the palpating finger, as observed during fluoroscopy. Studies of stasis, at twenty-four hours and forty-eight hours, often show a retention of the barium sulfate in the diverticulum.

In the roentgenologic differential diagnosis one must consider:

1. *Pseudo or Prestenotic Diverticulum*.—This deformity occurs with an ulcer of the first portion of the duodenum. The ulcer commonly has its origin in the duodenal bulb, and one can usually identify a niche or a crater.

2. *Localized Distention of the Second and Third Portions of the Duodenum*.—Such distention may be produced by a tight superior mesenteric vessel, which may present a picture suggesting true sacculatation. Similar dilatation may occur at the point of trifurcation of the gastric omental sac, where it forms the hepaticoduodenal ligament, the duodenocolic ligament and the hepaticoduodenocolic ligament. In both these conditions a stalk is not present. The enlargement is continuous with the long axis of the bowel. Furthermore, these dilatations can be readily recognized when the patient is examined both in the prone and the supine position. When the patient lies on his back, the distention of the duodenum becomes pronounced; when he assumes the prone position, the distention will be lessened or disappear entirely.

3. *Malignant Condition*.—Occasionally an annular carcinoma must be differentiated. In carcinomatous lesions there is distortion and discontinuity of the small bowel mucosa, whereas in a diverticulum the mucosa is continuous and undisturbed. The rarity of a malignant condition of the duodenum has been reported elsewhere.⁵

4. *Benign Tumors*.—A benign tumor is usually not confused with a diverticulum. As a rule it casts a negative shadow in contrast to the usual homogeneous dense shadow, produced by a diverticulum filled with barium sulfate.

In our experience, diverticulum of the duodenum occurred in 1.5 per cent of all patients examined.

CLINICAL ASPECTS

It is characteristic that patients exhibiting symptoms all have one symptom in common; i. e., distress during or after eating. Nearly all have been previously treated for ulcer or have submitted to surgical treatment for supposed disease of the gallbladder or appendix. Some have definitely been labeled as psychoneurotic in spite of a long history of dyspepsia and positive roentgeno-

logic evidence of duodenal diverticula. It is our belief that patients who present a history of dyspepsia, characterized by pain and fullness after meals, and in whom diverticula can be demonstrated radiologically, should be entitled to surgical extirpation of the lesion, if other causes have been eliminated. We feel that these patients should not be operated on until the history, physical

Fig. 1 (case 1).—A, preoperative roentgenogram. This shows a typical large diverticulum projecting from the mesial wall of the ascending limb of the duodenum (third part), demonstrating both the pouch and the stalk. On fluoroscopy, the diverticulum filled readily. Despite deep digital palpation, it could not be emptied. The diverticulum measured 3 cm. by 5.2 cm. The stalk measured 0.6 cm in diameter. B, roentgenogram taken twenty-four hours preoperatively. The stomach has completely emptied. Only fragments of the mediums are seen in the upper part of the small intestine. However, there was almost complete retention of the meal in the diverticulum. The stalk was again demonstrated, but its communication with the third portion of the duodenum was not seen on this hourly examination, thus indicating that the pouch did not affect the transit of the meal through the duodenal loop.

examination and roentgenologic and laboratory studies have eliminated other factors that could produce these symptoms, and, certainly, no patient should be operated on solely because of roentgenologic evidence of the diverticulum. In the following case reports, it will be noted that these criteria have been adhered to.

REPORT OF CASES

CASE 1.—A 48 year old business executive, who complained of dyspepsia and epigastric pain intermittently for fifteen years prior to examination, had been told previously that he had a duodenal ulcer. At various times he had been treated with alkalis, antispasmodics and ulcer diets. On occasion, he had been relieved by this treatment, but the symptoms always recurred with the slightest deviation from this routine. For the past year, in spite of rather rigorous conservative management, the patient had persistent pain and stated that he constantly suffered from indigestion. Roentgenographic examination (Conti) revealed a large diverticulum of the third portion of the duodenum (fig. 1).

At operation the diverticulum was resected (Stevens and Foltz) without opening of the duodenum. The pathologic report revealed acute and chronic diverticulitis with ulceration of the base.

Postoperative convalescence was uneventful. The patient at the time of writing had remained asymptomatic for approximately one year. Roentgenograms showed a normal duodenal pattern (fig. 2).

CASE 2.—A 33 year old fireman was admitted to the hospital on May 25, 1945, for medical observation. His chief complaint was that of epigastric pain following eating, which had persisted for some months despite medical treatment. Roentgenograms showed a small diverticulum of the duodenum. Because it is the general belief that a diverticulum of this size rarely produces symptoms, medical treatment was instituted, and the patient was kept under close observation. However,

the symptoms persisted. At the patient's request, surgical exploration was done (Stevens and Foltz) on July 11. The diverticulum was not evident; therefore the duodenum was opened longitudinally, and a diverticulum about 2 cm. deep was seen adjacent to the accessory pancreatic duct. The diverticulum was inverted and excised. The incision in the duodenum was closed transversely. Pathologic examination revealed ulceration of the base of the diverticulum, with polymorphonuclear and round cell infiltration. Convalescence was uneventful. The patient was completely asymptomatic following the operation and had remained so for the six months that follow-up was possible.

CASE 3.—A pharmacist's mate second class was admitted to the hospital on Oct. 23, 1945, with the chief complaint of epigastric pain following meals, which had persisted for four years prior to examination. In addition, nausea was present with the onset of the pain and, on many occasions, vomiting occurred shortly after the onset. There was a complaint of a tight full feeling in the upper part of the abdomen for about twelve hours following one of these typical attacks. In September, roentgenologic studies had revealed a duodenal diverticulum, when the patient was admitted to the hospital for operation. The patient's past history revealed that in January 1944 a cholecystectomy had been performed, with no relief of symptoms. Results of the physical examination were essentially negative throughout, except for some slight tenderness in the upper right quadrant of the abdomen. At operation (Stevens) the diverticulum was not seen until the duodenum was opened. A diverticulum adjacent to the duct of Wirsung was then seen, extending 1 inch (about 2.5 cm.) into the pancreas. The operative procedure was similar to that in case 2, opening the duodenum longitudinally, inverting the diverticulum and excising. The duodenum was closed transversely. Exploration had been done elsewhere, because of a roentgenologic diagnosis of duodenal diverticulum, and the diverticulum had not been observed. The pathologic report revealed a diverticulum lined by glandular mucosa, having a well marked muscularis mucosa and mucous glands under the muscularis mucosa resembling Brunner's glands, with chronic inflammatory exudate between the glands. The postoperative convalescence was uneventful, and the patient had remained free of symptoms for the three months during which follow-up was possible.

Fig. 2 (case 1).—Postoperative roentgenograms. It is apparent that there was no residual deformity of the duodenum and that the diverticulum was completely resected.

SUMMARY

Three cases of duodenal diverticula are reported. All 3 patients presented symptoms of dyspepsia, pain during or after eating and positive roentgenographic evidence of duodenal diverticula. Surgical extirpation of the diverticula afforded complete relief in all 3 cases, all other measures having failed. In 1 of these cases an ulcer was present in the base of the diverticulum. This diverticulum was located in the third portion of the

duodenum. In 2 cases the diverticulum could not be located until the duodenum was opened, because the diverticulum was a hidden projection into the pancreas.

CONCLUSIONS

1. The majority of duodenal diverticula do not produce symptoms and require no treatment.
2. Some diverticula of the duodenum produce symptoms which may be cured by surgical treatment.
3. It is sometimes necessary to open the duodenum to locate a diverticulum at operation.

EXCESSIVE HYPOPROTHROMBINEMIA DUE TO "DICUMAROL"

Its Treatment with Lyophilized Plasma

STUART W. COSGRIFF, M.D.

RICHARD J. CROSS, M.D.

and

DAVID V. HABIF, M.D.

New York

Twenty to 25 per cent of persons who receive "dicumarol" in the treatment of thromboembolic disease are hyperreactors to the drug, in that the conventional dosage produces an excessive elevation of the prothrombin time to levels at which hemorrhage may occur.¹ Bleeding takes place in approximately 6 per cent and is of major importance in 1 to 2 per cent, with occasional fatalities being reported.

Two therapeutic measures have been used in the management of dangerously elevated prothrombin times. First, large parenteral doses of synthetic vitamin K in the form of menadione sodium bisulfite² or vitamin K₁ oxide³ have been shown to reduce an excessive elevation of prothrombin time to safe range within twelve to forty-eight hours in approximately 85 per cent of persons. It thus appears that the results of this form of therapy are apparent only after a significant interval and may not occur at all in certain patients. Second, transfusions of whole fresh blood or fresh plasma have been employed when actual bleeding is taking place because of the delay and occasional failure to respond to the massive dosage of vitamin K. Some investigators⁴ have stated that no beneficial effect in reducing the prothrombin time or the degree of bleeding results from transfusion. Others⁵ report favorable results of transfusion both in lowering the prothrombin time and in decreasing the hemorrhagic tendency, with the recommendation that repeated transfusion may be necessary due to the transitory effect.

It was believed that the use of lyophilized plasma warranted a clinical trial in cases of hemorrhage

associated with excessive hypoprothrombinemia due to "dicumarol" because lyophilized plasma, reconstituted with 0.1 per cent citric acid and distilled water, has been shown by Strumia⁶ to possess a normal prothrombin content comparable with that of fresh whole blood. In addition, 500 cc. of plasma would have the equivalent effect of 1,000 cc. of whole blood in reducing the prothrombin time, inasmuch as the effective factors in combating the hypoprothrombinemia are considered to be situated in the plasma.

Although current sources of pooled lyophilized plasma introduce the potential risk of homologous serum hepatitis, this form of therapy has certain advantages that warrant consideration. In the first place, the general availability of this material where blood banks are not at hand justify its employment. Furthermore, problems of grouping do not arise in patients in whom sudden hemorrhage demands immediate control.

It is the purpose of this report to record observations on the efficacy of lyophilized plasma in reducing the excessive hypoprothrombinemia occurring in the course of "dicumarol" anticoagulant therapy.

MATERIALS AND METHODS

Determinations of prothrombin time were performed on whole plasma, according to a modification⁷ of Quick's technic,⁸ with commercially supplied rabbit lung as the source of thromboplastin, 0.1 molar sodium oxalate as the anticoagulant and 0.025 molar calcium chloride. Normal prothrombin time in this laboratory with the technic employed was found to be 14 (± 2)

TABLE 1.—Prothrombin Time and Activity of Random Samples of Reconstituted Lyophilized Plasma *

Specimen	Whole Plasma Prothrombin Time (Seconds)	Percentage of Normal Prothrombin Activity
1	13.5	100

seconds. The percentage of normal prothrombin activity was determined from a logarithmic prothrombin activity curve constructed according to Quick.

"Dicumarol" was administered in accepted dosage of 300 mg. on the first day, 200 mg. on the second day and subsequent daily dosage depending on the results of the prothrombin time of that day. It was attempted to prolong the prothrombin time to an optimal reading of 27 seconds, which is 20 per cent of normal activity. The effective therapeutic range was

considered to be between 22 and 44 seconds, which is respectively 30 per cent and 10 per cent of normal activity. In this series of patients with thromboembolism who were treated with anticoagulants, hemorrhage has rarely occurred below 44 seconds, 10 per cent of normal activity.

RESULTS

The previous observations⁶ on the prothrombin content of lyophilized plasma were confirmed. It was noted that the prothrombin activity of these random samples averaged between 75 per cent and 100 per cent of normal (table 1).

On the basis of this finding, lyophilized plasma in doses of 500 cc. was administered to patients in whom an excessive hypoprothrombinemia had occurred during "dicumarol" therapy. The results in 13 patients are presented in table 2. In this group hemorrhage of significant severity was not taking place at the time of transfusion, so that observations as to the effect of the plasma on actual bleeding were not possible. The lyophilized plasma was effective in producing an immediate reduction of prothrombin time to safe range. It was apparent that an upswing toward the pretreatment level occurred as soon as six hours in some

patients, similar to the transient effects following whole blood transfusion as previously reported.⁶ It is thus evident that, pending the more permanent but delayed effects of vitamin K, repeated plasma infusions may be essential to maintain a prothrombin time in the safe range.

SUMMARY

It has been confirmed that lyophilized plasma, reconstituted with 0.1 per cent citric acid solution, contains normal prothrombin activity. This plasma is effective in producing an immediate reduction of prothrombin time to safe range in persons with excessively elevated levels due to administration of "dicumarol." Effective reduction in prothrombin time may be maintained for as little as six hours, thus necessitating multiple transfusions in certain instances. Pooled lyophilized plasma should be employed only when grouped fresh blood is not available owing to the added risk of transmission of homologous serum hepatitis.

EFFECT OF UREA ON BACTERICIDAL ACTION OF SULFONAMIDE DRUGS

Report of Five Cases of Bacterial Meningitis

A. A. LA LONDE, M.D.
Austin, Texas

and
W. JAMES GARDNER, M.D.
Cleveland

In 1942 Tsuchiya¹ and his co-workers reported in vitro experiments with urea and the sulfonamide compounds which indicated that the inhibitory effect of sulfadiazine on the growth of *Escherichia coli* is significantly increased by the presence of urea, even when methionine, a sulfonamide inhibitor, is present.

They extended their observations to other sulfonamide compounds, using para-aminobenzoic acid as the sulfonamide inhibitor, and also showed that three strains of sulfathiazole-resistant staphylococci in a synthetic medium were susceptible to urea-sodium sulfathiazole combinations. They attributed this beneficial effect of urea to its inhibition of the sulfonamide inhibitors and to an enhancement of the bacteriostatic action of the sulfonamide compounds.

The development of sulfonamide resistance by bacteria has become significant, and any agent which may overcome this resistance may play an increasingly important role. McLeod² showed that the development of sulfapyridine fastness in a strain of *Pneumococcus* type I is accompanied by a greatly increased production of sulfonamide inhibitor. Schmidt³ and his co-workers have shown that strains of *Pneumococcus* type I and type III can be made resistant to sulfapyridine in vitro and in vivo in mice. Vivino and Spink⁴ reported 2 cases of staphylococcal bacteremia, both strains becoming markedly sulfonamide resistant, one after only eight days of therapy.

The mechanism of bacterial inhibition by the sulfonamide compounds may be due to a depression of the enzyme reaction in the bacterial cell. Green⁵ has produced bacterial extracts containing a proliferation factor which powerfully stimulates the reproductive rate of many bacteria, and it is believed that this proliferation factor stimulates the same enzyme reaction in the bacterial cell which sulfonamide compounds inhibit. The sensitivity to sulfanilamide of any bacterial strain may be conditioned by the rate at which the autolysing organism liberates this "P" factor. The effect of urea on this factor is unknown. It is known that urea renders sulfonamide compounds more soluble and that it also has a solvent action on pus, debris and necrotic tissue which act as sulfonamide inhibitors.⁶ Urea has the additional advantages of being relatively nontoxic.

Mr. Alfred Reich cooperated in the bacteriologic studies. From the Cleveland Clinic. Dr. LaLonde was formerly Staff Assistant, Department of Neurosurgery.

mildly bacteriostatic, diuretic, simple to administer and inexpensive.⁷

Clinical reports appeared which tend to confirm the laboratory experiments. Schnitker and Lenhoff⁸ employed urea and sulfadiazine or sulfathiazole in the treatment of 40 patients with sulfonamide-resistant gonorrhea, among whom 52.5 per cent cures were reported. However, they administered only 30 Gm. of urea orally daily, which by present standards is a minute dose.

In 1945 Ecker⁹ reported his experiences with the use of urea and the sulfonamide compounds in the successful treatment of a case of meningitis due to *Esch. coli* which failed to respond to penicillin and sulfadiazine.

In 1946, Vesell, Gross and Sussman¹⁰ reported the use of urea and sodium sulfadiazine intravenously in the successful treatment of a case of subacute bacterial endocarditis which had failed to respond to sulfadiazine alone. They stressed the importance of increased solubility of sulfadiazine in the urine with reduction of sulfadiazine crystalluria when urea is given with massive doses of sodium sulfadiazine.

REPORTS OF CASES

CASE 1.—A man, aged 43, contracted meningitis due to *Alcaligenes faecalis* after the breaking down of his operative wound following removal of a large sacral meningocele. For three months after operation large doses of sulfadiazine orally and penicillin intramuscularly and intrathecally were given in an attempt to prevent localized meningitis at the operative site from spreading. However, on Dec. 26, 1945, *A. faecalis* was grown from spinal fluid. Despite the continued use of sulfonamide compounds and penicillin intramuscularly and intrathecally, spinal fluid cultures remained positive and the patient's condition grew steadily worse. Streptomycin was then tried by intrathecal injection; although this drug temporarily sterilized the spinal fluid it had to be discontinued because of excruciating leg pain when injected into the lumbar subarachnoid space, and head pain when injected into the cisterna magna. By Feb. 28, 1946, the patient was in extremis. Up to this time he had received a total of 39,256,000 units of penicillin intramuscularly and 12,546,000 units intrathecally, 347.5 Gm. of sulfadiazine orally and intravenously, and 200,000 units of streptomycin intrathecally.¹¹ He was then started on urea, 30 Gm. orally every four hours, and penicillin was continued as before, 30,000 units intramuscularly every three hours. Sulfadiazine, which had been discontinued four days previously, was again started, 2 Gm. every four hours.

Temperature returned to normal in twenty-four hours and culture of spinal fluid was sterile four days after starting urea. Cell count in the spinal fluid dropped from 2,300 polymorphonuclear cells to zero in that time. Spinal fluid on two subsequent examinations was sterile; one specimen contained 3 lymphocytes and one 15 lymphocytes. The patient became alert and after fifteen days of this therapy was discharged (the chart). The patient returned to his job one month later and has remained well. Blood urea during urea therapy ranged from 24 mg. per hundred cubic centimeters to a maximum of 180.¹² The only symptoms attributed to

the elevated blood urea were somnolence and loss of appetite. Blood sulfadiazine level ranged from 4.1 mg. per hundred cubic centimeters to 16.5 before urea was given and a maximum of 13.5 after it was started. The response in this case was dramatic and undoubtedly due to the combined use of urea and sulfadiazine.

CASE 2.—A man, aged 53, contracted meningitis due to *Klebsiella pneumoniae* after removal of an acoustic neuroma on Sept. 12, 1946. Because the mastoid process was entered during the operation he was given a prophylactic course of penicillin, 30,000 units intramuscularly at three hour intervals for six days. Because of continued fever a second course of penicillin was started on the fifteenth postoperative day. On the eighteenth postoperative day, spinal puncture disclosed viscid, brown, turbid fluid which on culture grew *K. pneumoniae*. Accurate cell count could not be made. He was started on sulfadiazine, 1 Gm. every four hours. On the twentieth postoperative day penicillin was discontinued and 30 Gm. doses of urea every four hours were started with sulfadiazine dosage continued as before.¹³ Six days after starting this therapy spinal fluid culture was still positive, but on the ninth day it was sterile, temperature reached normal and therapy was stopped. He was discharged four days later. He returned to his job and was in good health when seen

The chart shows the effect of introducing urea into the therapy of case 1. Similar records were kept for the other cases.

six months after discharge. The recovery in this case was unequivocally due to the combination of urea and sulfadiazine, as the patient received no other therapy during the period of response.

CASE 3.—A man, aged 31, on July 16, 1946, sustained a compound, comminuted skull fracture in the right parietal region extending into the right petrous bone, with resulting cerebrospinal fluid rhinorrhea and otorrhea, and Bell's palsy on the right side. His scalp wound was sutured. Sulfadiazine in doses of 1 Gm. orally every four hours and penicillin 30,000 units intramuscularly every three hours were started as a prophylactic measure. On the seventh day the otorrhea ceased, and the scalp wound was found to be infected. Lumbar puncture on the eighth day revealed a pressure of 290 mm. water, and the fluid contained 1,600 polymorphonuclear cells with *Esch. coli* on culture. A secondary debridement of the scalp was performed and urea was started in doses of 30 Gm. orally every four hours in addition to the sulfadiazine which the patient was already receiving. Penicillin was discontinued, a total of 2,160,000 units having been given. Fifty thousand units of streptomycin was injected intrathecally at twelve hour intervals on the first four days of urea therapy. These injections always caused severe leg pain and were discontinued. On the third day of urea therapy spinal fluid culture was

9. Ecker, A. D.: Urea and Sulfonamide Treatment of Bact. Coli Meningitis, *Lancet* **1**:176-177 (Feb. 10) 1945.

10. Vesell, H.; Gross, I. H., and Sussman, R. M.: Urea as an Adjunct to Sulfonamide Therapy: Report of Its Successful Use in Case of Subacute Bacterial Endocarditis, *J. Lab. & Clin. Med.* **31**:444-452 (April) 1946.

11. This patient had several generalized convulsions twelve days after the intrathecal injection of streptomycin and while receiving penicillin intrathecally. He has had petit mal attacks since his discharge until recently.

12. On one occasion simultaneous samples of blood and spinal fluid revealed blood urea of 111 mg. per hundred cubic centimeters and spinal fluid urea of 195 mg. per hundred cubic centimeters.

13. The bitter taste of urea was masked somewhat by giving it in cold fruit juice.

still positive, but it was sterile on the fifth day and on three subsequent examinations. Sulfadiazine and urea were discontinued after fifteen days of therapy and the patient was discharged. In this case the patient contracted meningitis due to *Esch. coli* while on penicillin and sulfadiazine. Spinal fluid cultures remained positive during the administration of streptomycin and subsequently became sterile while the patient was receiving urea and sulfadiazine.

CASE 4.—A boy aged 6 months contracted an infection of the respiratory tract on March 17, 1947. On March 18, his temperature was 105 F. and he began vomiting. On March 22 he had a generalized convulsion. He was hospitalized and a diagnosis of pneumococcal meningitis was made. He was given 2 Gm. of sulfadiazine daily, and 20,000 units of penicillin intramuscularly every three hours and 25,000 units intrathecally daily. There was gradual improvement, and the spinal fluid cell count dropped from 25,000 to 10. He was discharged on April 12.

On April 24 symptoms of meningitis recurred. He was transferred to Cleveland Clinic on April 28. His temperature was 104 F., the anterior fontanel was bulging, there was spasticity of the extremities, and moderate opisthotonus. Ventricular fluid on this date contained 500 polymorphonuclear cells and 102 mg. protein and grew *Staphylococcus albus*. On the day of entry, urea and sulfadiazine were started, 0.5 Gm. and 0.25 Gm. respectively, through a stomach tube. On the second day of therapy a small, flexible, plastic tube was introduced through a needle into the lumbar spinal canal for continuous drainage. On the third day the temperature was 102.4 F., and the spinal fluid collected from the indwelling tube contained 300 polymorphonuclear cells. Dosage of urea and sulfadiazine was reduced to every eight hours. Fluid collected on the fifth day contained 150 polymorphonuclear cells and was sterile. On the eighth day the plastic tube ceased to function and was removed. Temperature at this time was normal. Sulfadiazine and urea were discontinued on the twelfth day. Fluid removed by cisternal puncture on the sixteenth day contained 1 cell and 33 mg. protein, and was sterile. The patient was discharged on the eighteenth day and was last seen six weeks later. At this time he was found to have some neurologic sequelae of the infection but the anterior fontanel was soft and there was no fever. The significance of this case is difficult to evaluate in view of the debatable identity of the responsible organism, but the clinical response to therapy is unquestionable.

CASE 5.—A girl aged 5 months was admitted to Cleveland Clinic on May 20, 1947, for treatment of congenital communicating hydrocephalus. In preparation for operation, continuous spinal drainage was instituted by means of a small, flexible, plastic tube introduced through a needle into the lumbar spinal canal on the third hospital day. A benzalkonium chloride dressing over the tube became contaminated with feces, and on the eleventh day temperature rose to 104.5 F. The anterior fontanel was tense. Fifteen thousand units of penicillin intramuscularly every three hours was started. Temperature remained elevated and on the thirteenth day the tube in the spinal canal was removed, as it had ceased to drain. Ventricular fluid contained 58 polymorphonuclear cells but was sterile. Penicillin was discontinued on the fifteenth day because of failure to control the fever. On the sixteenth day ventricular fluid contained no cells but grew *Esch. coli* on culture. On the twenty-second day ventricular fluid again grew *Esch. coli*, and sulfadiazine and urea, 0.2 Gm. and 0.5 Gm. respectively, were administered every three hours through a stomach tube. On the twenty-fourth day ventricular fluid was still positive for *Esch. coli* and contained 51 polymorphonuclear cells. Temperature became normal on the twenty-sixth hospital day, although the fluid culture remained positive until the thirtieth day. An operation for hydrocephalus was carried out on the thirty-fifth day. Urea and sulfadiazine were discontinued two days later when the temperature became normal. The patient was discharged on the ninth postoperative day with no evidence of infection. The response to the therapy in this case was unequivocal.

SUMMARY

We have successfully treated with urea and sulfadiazine a case of meningitis due to *Alcaligenes faecalis* which did not respond to penicillin and sulfadiazine, and in which streptomycin was not tolerated; a case of meningitis due to *Klebsiella pneumoniae*, which developed while the patient was receiving prophylactic doses of penicillin; 2 cases of meningitis due to *Escherichia coli* as well as a case of meningitis probably due to *Staphylococcus albus*. Since this form of therapy is simple, safe and effective it should be tried in sulfonamide-resistant infections before resorting to streptomycin.

A case of tuberculous meningitis and 1 case of meningitis due to *Torula* failed to respond to urea and sulfadiazine.

AUREOMYCIN: A NEW ANTIBIOTIC WITH VIRUCIDAL PROPERTIES

I. A Preliminary Report on Successful Treatment in Twenty-Five Cases of Lymphogranuloma Venereum

LOUIS T. WRIGHT, M.D.

MURRAY SANDERS, M.D.

MYRA A. LOGAN, M.D.

AARON PRIGOT, M.D.

and

LYNDON M. HILL, M.D.

New York

As a result of a comprehensive screening program at the Lederle Laboratories Division, American Cyanamid Company, a substance has been obtained from a *Streptomyces* which gave promise of possessing unusual antibiotic properties. The antibiotic has been named aureomycin, and a statement regarding its specific properties and chemical purification will be published elsewhere.¹ Of special interest to us was the striking spectrum of activity exhibited by this antibiotic against many rickettsiae and certain viruses.² In particular, it was noted that aureomycin was highly effective in the treatment of mice infected intracerebrally with the virus of lymphogranuloma venereum.

In view of the information made available to us concerning the unusual therapeutic range of aureomycin, it seemed desirable to use this antibiotic in human beings suffering from lymphogranuloma venereum. An added incentive to the study was the realization that effective treatment has not been available for this disease. Although claims have been made for the efficacy of numerous compounds,³ including various sulfonamide drugs, antimony potassium tartrate, penicillin and stibophen ("fuadin"), it is generally agreed that only secondary infections are affected by the compounds in question, whereas the basic disease process due to the viral agent remains untouched.

Since a large percentage of the patients acutely afflicted with this virus disease become chronic sufferers of a progressive, fibrotic and destructive process, the need to provide specific therapy is apparent. Twenty-five cases of lymphogranuloma venereum were selected for this study and were divided into three groups: (1) buboes, (2) lymphogranulomatous proctitis, with or without ulceration, and (3) benign cicatricial rectal strictures.

Dr. Y. Subbarow gave us suggestions throughout the course of this study and supplied the aureomycin that was used.

From the Surgical Department of Harlem Hospital, Department of Hospitals, New York, and the Ophthalmological Department, College of Physicians and Surgeons, Columbia University, New York.

3. Wright, L. T.; Freeman, W. A., and Bolden, J. V.: Lymphogranulomatous Strictures of Rectum, Arch. Surg. 53: 499-544 (Nov.) 1946.

METHOD OF STUDY

Manner in Which the Cases Were Followed.—1. History: A detailed history was taken, with special emphasis on the initial appearance and progress of the local lesion.

2. Physical Examination: A complete physical examination was made which embraced (a) examination of local lesion by observation, palpation and mensuration, (b) proctoscopic examination in rectal cases wherever possible, (c) biopsies in all cases where possible and (d) aspiration of buboes with touch preparations, smears and cultures.

3. Laboratory Studies: The laboratory studies carried out were: (a) urinalyses, (b) hematologic studies—red blood cell count, white blood cell count, hemoglobin estimation and hematocrit determinations, (c) Kahn tests of the blood, (d) chemical studies of the blood—determinations of urea nitrogen, creatinine, glucose plasma proteins, albumin-globulin ratio, alkaline and acid phosphatase, (e) Frei tests, (f) complement fixation tests for lymphogranuloma venereum, (g) tests of hepatic function—icteric index, Van den Bergh, thymol turbidity and cephalin flocculation tests, (h) bone marrow smears, (i) serum levels of aureomycin before and after treatment, (j) bacteriologic cultures, (k) smears for inclusion bodies, (l) histologic examination of biopsy material and (m) barium enemas in cases of rectal stricture. For every patient a detailed history was taken and complete physical examinations were made. Examination of urine, red and white blood cell counts, hemoglobin estimation, Kahn test, Frei test and urea nitrogen, creatinine and glucose determinations were made in all cases. The other tests were done in a sufficient number of cases to give us adequate information as to possible harmful effects that the drug might have.

4. Drug Administration: Aureomycin, as furnished by the Lederle Laboratories, is a yellowish crystalline substance in sterile sealed vials containing 20 mg. A special diluent furnished with the drug was used in our early cases. In our later cases, the drug was dissolved in 2 cc. of isotonic sodium chloride solution. The intramuscular route of injection was used. Daily dosage in some cases was 10 mg., in some cases 20 mg. and in 1 case 40 mg.

CASES STUDIED

Buboes Due to Lymphogranuloma Venereum.—There were 8 patients in this group with buboes due to lymphogranuloma venereum, all of whom were Negro men. Their ages varied from 22 to 31 years. The specific lesions had been present in 7 cases two weeks to two months and in 1 case for two years. In 7 patients the bubo was the only pathologic observation, while 1 patient had associated proctitis with rectal bleeding. The nodes varied in size from that of a large pea to that of an egg and were unilateral in all instances. The nodes were removed in 5 cases, and the histologic observations were compatible with lymphogranuloma venereum. Aspiration biopsy for smears and cultures were bacteriologically sterile. Smears for inclusion bodies were made in all cases.

Reactions to Frei tests were positive in all patients with buboes. The reaction to the complement fixation test for lymphogranuloma venereum was 4 plus in a 1:40 dilution in 2 cases. (A butchers' strike at this time made it impossible to obtain sheep cells for the other cases.) The Kahn reaction was 2 plus in one instance and 4 plus in another. Six reactions to Kahn tests were negative. The results of urinalyses were normal throughout the study. Urea nitrogen, creatinine, sugar and plasma protein determinations remained within normal limits throughout the period of the study. Albumin-globulin ratios remained unchanged. In 5 of these cases, after treatment, the following tests of hepatic function were carried out: icteric index, Van den Bergh, thymol turbidity and cephaline flocculation tests. All observations were normal. The treatment for 7 of the patients in this group consisted of a single daily intramuscular injection of 20 mg. of aureomycin. In 2 of the cases the patients were given one injection of 20 mg. of aureomycin into the bubo along with the regular treatment.

RESULTS

All patients showed a reduction in the size of the gland after four days of treatment with aureomycin, an event which in our experience over twenty-four years with several hundred cases of early lymphogranuloma

venereum has never occurred spontaneously within so short a time. The patient that had rectal bleeding in addition to the bubo reported no further rectal bleeding after three days of treatment with aureomycin (table 1).

Effect of Aureomycin on Cellular Inclusions.—When properly coordinated with clinical and laboratory observations, the presence of cytoplasmic morphologic units consisting of inclusion, elementary and initial bodies may be considered pathognomonic of lymphogranuloma venereum. However, failure to demonstrate these bodies, which appear purplish red with Giemsa stain, does not preclude an active lymphogranulomatous process; for in some instances the demonstration of the inclusions may be somewhat fortuitous, depending on the stage of the infection and the portions of the lesions which are studied microscopically.

With these qualifications in mind, the following observations were made on touch preparations and smears. Smears for inclusion studies came from aspiration material, tissues of buboes and biopsy specimens taken from subacute or chronic infections in cases of rectal disease. Eleven cases were observed, and in each

TABLE 1.—Effect of Aureomycin on Eight Patients with Lymphogranulomatous Buboes

Case No.	Size of Bubo on Admission, Before Treatment, Cm.	Microscopic Observations* (Giemsa Stain) Before Treatment	Size of Bubo After Four Days' Treatment, Cm.	Microscopic Observations (Giemsa Stain) After Treatment of Bubo
1	4 by 7		2 by 2	Aspiration bacteriologically sterile
2	5 by 3	Numerous elementary bodies with occasional initial bodies	1.5 by 3	48 hr.: occasional elementary and initial bodies; 1 week later: no inclusion or elementary bodies; aspiration bacteriologically sterile
3	2.5 by 4		Not palpable

6	3 by 0.5		2 by 2	Aspiration bacteriologically sterile
7	5 by 5	As in case 2	4 by 4	As in case 2
8	7 by 5		5 by 4	As in case 2

* In cases 1, 2, 4, 5 and 6 the remnants of the nodes were excised and studied histopathologically; the general pathologic appearance was compatible with lymphogranuloma venereum.

instance a series of specimens was taken. In the cases of bubo, preparations were made before, during and after treatment. Of eight Giemsa-stained preparations studied microscopically, three were seen to contain various morphologic units associated with this virus disease (table 1). The three specimens with positive reactions came from the eight buboes. In 1 instance (case 2) numerous elementary bodies, with an occasional initial body, were noted both in inclusion formation and lying free in the cytoplasm. In this specimen taken from the acute lesion the day of the patient's admission to the hospital, the elementary bodies appeared uniform and took the stain well. Within forty-eight hours after the beginning of treatment a specimen taken from the same bubo revealed only occasional elementary and initial bodies and both units appeared pleomorphic and stained poorly. A third specimen, taken from the same site a week after treatment had been started, contained no inclusion or elementary bodies. While this observation may not be independently significant, it is worthy of note, in view of the patient's rapid clinical improvement. In two other buboes (cases 5 and 7) the described experience was repeated with serial specimens.

Proctitis Due to Lymphogranuloma Venereum.—There were 3 cases of proctitis due to lymphogranuloma venereum in this group, 2 women and 1 man, whose

ages were, respectively, 22, 25 and 27 years. Presenting symptoms were rectal pain, discharge which had been present for three weeks, one year and two years, respectively. Two patients had rectal bleeding. All 3 patients had no associated lesion or other manifestation of this disease. Results of physical examination were essentially negative except for the local pathologic condition. Each patient showed profuse purulent foul-smelling rectal discharge with rectal tenderness on examination. In 1 case there was blood on the examining finger. Proctoscopic examination in all 3 cases revealed a granular mucosa with areas of yellowish exudate. In 1 case the granular area bled very easily. Biopsy in 2 cases showed tissue with acute inflammatory reactions.

either a reinfection or a recurrence. After a second period of treatment, with a total dose of 60 mg. of aureomycin, the discharge disappeared. An examination ten days later showed no recurrence.

Benign Lymphogranulomatous Rectal Stricture.—In this group 14 patients were studied, 13 women and 1 man. Five of these patients had previously had a colostomy for obstruction; 1 patient had a retrovaginal fistula. The ages of the women ranged from 28 years to 57 years, and the man was 27 years. All the cases had been studied previously, and biopsy showed the usual pathologic observations. The duration of the lesions varied from two years to twenty-six years, the average being nine and two-tenths years. There were no significant associated diseases in this group.

TABLE 2.—Effect of Aureomycin on Rectal Strictures Due to Lymphogranuloma Venereum

Case No.	Duration (Yr.)	Days on Service	Dosage		Rectal Pathologic Condition on Admission	Clinical Condition After Start of Treatment	Condition on Discharge
			Mg. per Day	No. Days			
12	16	37	10	21	Stricture did not admit finger tip; colostomy; pain and discharge from rectum	No rectal discharge or pain on eleventh day	Stricture admitted finger tip; no pain or discharge; smooth rectal mucosa
13	16	27	10	21	Stricture did not admit finger tip; pain and profuse discharge; perirectal tenderness; colostomy	No perirectal tenderness or discharge on eighth day	Slight rectal discharge; no perirectal pain; stricture unchanged
14	10	37	10	21	Stricture did not admit finger tip; rectal discharge	No rectal pain and defecation easy (first time in ten years) on eighth day	Stricture softer; admitted finger tip; diameter of stool double since treatment
15	26	50	20	50	Stricture did not admit finger tip; profuse rectal discharge; severe rectal pain	Pain and discharge slight on seventh day	No rectal pain or discharge; no change in size of stricture
16	2	44	20	28	Stricture did not admit finger tip; stricture interrupted by recto-vaginal fistula 2 cm. diameter	By the sixteenth day there had been no gas or feces per vaginam for 48 hr.	Rectal and vaginal observations unchanged; no gas or feces per vaginam as on admission.
17	3	32	20	31	Stricture did not admit finger tip; decided decrease in stool diameter, 1 to 1.5 cm.	Stool diameter increased, subjectively improved on twelfth day	Diameter of stool double since treatment
18	7	13	20	5	Stricture did not admit finger tip; decrease in diameter of stool	No change in stricture on fourth day	Diameter of stool increased; no changes in rectal observations
19	4	31	20	31	Stricture did not admit finger tip; bleeding and pain; discharge	No rectal bleeding on the fourth day	Diameter of stool doubled since treatment; no rectal bleeding or pain
20	2	25	20	23	Stricture did not admit finger tip; profuse purulent discharge from rectum; rectal pain; colostomy	Rectal discharge reduced at least 50 per cent by the second day	Stricture unchanged; no rectal bleeding or pain; no discharge
21	2	16	20	16	Stricture admitted index finger; band 0.5 cm. wide in stricture; pain and bleeding on defecation	Diameter of stool greatly enlarged by the seventh day	Stricture not present; no rectal pain or bleeding
22	10	30	20	16	Stricture did not admit finger tip; rectal discharge; diameter of stool diminished	Diameter of stool doubled by the sixteenth day	No change in stricture; no rectal discharge or pain; stools doubled in diameter
23*	6	11	20	10	Stricture admitted finger tip; colostomy; profuse purulent discharge		No change in stricture; only slight rectal discharge
24	10	12	20	11	Stricture did not admit finger tip; decrease in size of stool	Fifth day drug administration: increased size of stool by fifth day	Stricture unchanged; stools doubled in diameter
25	10	14	20	12	Stricture did not admit finger tip; decrease in diameter of stool	Moderate increase in stool diameter by sixth day	No change in rectal stricture; stool diameter doubled

* The patient went home against advice after nine days of treatment.

Reaction to Frei tests were positive in all cases of lymphogranuloma proctitis. Complement fixation tests for lymphogranuloma venereum were 4 plus in dilution of 1:40 in 2 cases. In the third case this test was not done, because of a shortage of sheep cells. Results in all other laboratory studies were observed to be within normal limits throughout the study.

Two patients had eosinophilia; in 1 patient there were 7 per cent and in the other patient 4 per cent eosinophils after treatment. Two patients had leukocytosis which disappeared while the patients were under treatment. Each of these patients was given a daily intramuscular injection of 20 mg. of aureomycin. The total doses given were 80 mg., 200 and 220 mg.

Clinically these patients showed decided improvement. In 2 cases, after four days of treatment, tenderness and discharge disappeared; in the third case, rectal bleeding disappeared after the eighth day of treatment. Proctoscopic examinations at the end of treatment in the 3 cases revealed no abnormalities of the rectal mucosa. One patient, readmitted seventeen days later, complained of rectal discharge, which was considered

History on admission showed that 5 patients complained of rectal pain, 2 had rectal bleeding and 7 had rectal discharge. Four patients who did not have a colostomy stated that the diameter of the stool was decreased. One patient complained of passage of gas and feces *per vaginam*.

Physical examination on transfer to this service for study showed, on rectal examination, 5 cases with rectal tenderness, 7 cases with rectal discharge and 2 with blood on the examining finger. The strictures were so advanced, that with the exception of 2 cases, not even the tip of the finger could be admitted into the rectum at the time of admission.

All patients studied had negative Kahn reactions and positive reactions to Frei tests. The result of the complement fixation test for lymphogranuloma venereum in 10 cases was 4 plus in 1:40 dilution, and in 1 case it was 3 plus in 1:5 dilution. Three patients were not tested.

The patients in this group received daily intramuscular injections of aureomycin in amounts of 10 or 20 mg.. The total dose ranged from 160 mg. to 1.0 Gm.

Clinical Course.—As may be noted from table 2, in this group with chronic infections of long duration, the response to antibiotic therapy was gratifying. On the second day of treatment, 1 patient reported considerable decrease in the rectal discharge, while another showed complete cessation of rectal discharge and bleeding by the fourth day of treatment. Five patients showed increase in diameter of stools on the fifth, sixth, seventh, twelfth and fifteenth days of treatment, respectively. Four patients reported decrease in rectal pain and discharge on the seventh, eighth and eleventh days of treatment, respectively. The patient with the rectovaginal fistula had no further passage of feces or gas *per vaginam* after the sixteenth day of treatment.

Examination during and at the end of treatment in 11 cases showed no change in the rectal stricture. One patient that had previously exhibited a small 0.5 cm. band showed no evidence of the band following treatment. Two strictures had become softer and admitted the tip of the examining finger.

Six patients showed stools twice their previous diameter, and 2 patients showed a slight increase in the diameter of stools.

Two patients with rectal bleeding had no bleeding at the end of treatment. Six patients with rectal discharge had no discharge at the end of treatment, and there was decided reduction in 2 cases.

In the 6 patients with rectal pain, all rectal tenderness had disappeared while they were under treatment.

The Anemic Factor.—Since the present study constitutes the first use* of aureomycin in human beings, every effort was made to follow the various body systems in each person under treatment. Within a short time after the investigation had been started, anemia was noted in patients receiving aureomycin. Further study revealed the following facts.

In the early cases, the antibiotic was dissolved in a special diluent designed to maintain a low pH , which was considered desirable. Anemia developed in all patients who received injections with this material (table 3). However, when the special diluent was replaced by isotonic sodium chloride solution the anemia either did not occur at all or, if present, was much less apparent and made its appearance more slowly than formerly. In all instances, even with the use of the special diluent, when a folic acid-iron compound ("folvron") was administered simultaneously with the aureomycin, no anemia was noted.⁵

A critical hematologic evaluation of the anemia made it clear that we were dealing with a simple hypochromic condition of the peripheral blood. That the hemopoietic system was not injured was apparent from the results of bone marrow studies and from the course of the anemia. It should also be noted that blood chemical values were normal in all cases; tests of hepatic function (made in 13 cases) revealed no abnormalities. The urine was consistently normal in all cases throughout the study. Results of tests of renal function (3 cases) were normal. Hematocrit values (20 cases) were normal. The only positive observation was eosinophilia in 18 cases, with the level of eosinophils ranging from 4 to 19 per cent during treatment.

In general, it may be said of aureomycin suspended in isotonic sodium chloride solution that the anemic factor, when it functioned, produced mild easily rectified

hypochromia of the peripheral blood. In the absence of apparent toxic effects on any other body system and in the presence of the potent antibiotic activity of aureomycin, the anemia was considered sufficiently minor to warrant continued use of the substance under investigation.

Aureomycin Blood Levels.—Since the schedule of treatment in this report consisted of very small amounts of aureomycin in proportion to body weight, i. e., 10 or 20 mg. daily in adults weighing 50 to 70 Kg., it was of interest to determine (a) whether any of the antibiotic was in the blood stream and (b) if present in circulating blood, how long the antibiotic remained there.

TABLE 3.—Effect of Aureomycin on Peripheral Blood

* Discharged eight days after the start of aureomycin therapy.

† No folic acid-iron compound given at any time.

The technic for estimating the presence of aureomycin in the circulating blood is similar to the inhibition tests used with streptomycin. Details of this test will be published elsewhere.

For present purposes it will be sufficient to describe the manner in which blood samples were collected and to state the results of the blood analyses which were carried out at the Lederle Laboratories.

In accordance with instructions, all blood samples were drawn in amounts of about 15 cc. into rubber-stoppered sterile test tubes. As soon as possible, each tube was quickly frozen by immersion into a mixture of equal parts of methyl alcohol and acetone which contained solid carbon dioxide. The frozen blood was then stored in a refrigerator (solid carbon dioxide) until tested.

In this manner, blood was collected from 7 patients (cases 17, 22, 23, 5, 6, 7 and 10) receiving 20 mg. of aureomycin once daily. In the case of 3 patients, blood was taken at two, six and ten hour intervals after

4. This paper was submitted for publication on May 4, 1948.

5. Since this study was presented for publication, numerous patients suffering with lymphogranuloma venereum and other diseases have been treated with aureomycin. It can now be definitely stated that the anemic factor seen in this first study represented an effect due to the special diluent and not to the antibiotic.

injection of aureomycin. In the remaining 4 cases, the blood samples were drawn just before injection of the antibiotic and two, six and ten hours thereafter.

The blood values representing circulating aureomycin in specimens described were not considered significant.⁶ It is to be noted that the present schedule of treatment represented the first tentative approach to therapy; consequently, very small amounts of aureomycin were used and the amount of circulating antibiotic in the blood was not accurately demonstrable by present methods of assay.

SUMMARY

A preliminary study of 25 patients with lymphogranuloma venereum treated with aureomycin, a new antibiotic, is reported. Eight patients with buboes were treated and showed a decided reduction in size of the node at the end of four days of treatment. In 3 instances, on admission of the patients, smears from aspiration of the bubo revealed inclusion and elementary bodies which appeared uniform and took the stain well. Within forty-eight hours after the start of treatment, specimens from the same buboes revealed only occasional elementary and inclusion bodies and both units appeared pleomorphic and stained poorly. One

6. Dornbush, A.: Personal communication to the authors.

week after treatment, no elementary or inclusion bodies were seen.

Three patients with proctitis were treated and showed decided improvement, in 2 instances after four days and in the third case after eight days. Proctoscopic examination at the end of treatment showed normal rectal mucosa. Fourteen patients with benign rectal stricture due to lymphogranuloma venereum were studied and showed a decided change in the fibrous rectal stricture, although there was decided decrease in rectal pain, discharge and bleeding. There was an increase in the diameter of the stool.

CONCLUSION

On the basis of our past experience, we believe that in 25 cases of lymphogranuloma at this hospital there were multiple strains of the virus. There is, therefore, the possibility that the effective antibiotic activity of aureomycin is not limited to a single strain.

Aureomycin, a new antibiotic, with apparent virucidal properties, has been used in human beings for the first time. The clinical results in the three types of lymphogranuloma venereum discussed in this paper showed such results as to warrant further extensive research and clinical trial of the antibiotic.

GENERAL PRACTITIONERS SESSION

CARCINOMA OF THE PROSTATE GLAND

C. D. CREEVY, M.D.
Minneapolis

Carcinoma of the prostate gland is an insidious and deadly disease of slowly increasing frequency. While there were only 83 cases discussed in the literature up to 1899, by 1935 Rich had observed the condition in 14 per cent of autopsies on men, and Moore expressed the belief that he could recognize it in 21 per cent of men past 40. By 1941 Baron and Angrist had claimed that they had observed occult forms in 46 per cent of 50 men past 50 years of age in consecutive autopsies. Using these figures, and assuming that there are 17,000,000 men past 50 in the United States, Hinman has estimated that there must be between 3,000,000 and 8,000,000 cases in this country at any one time. Carcinoma of the prostate gland is listed as the cause of 15,000 to 20,000 deaths in the United States each year (Jewett). To it Huggins attributed 5 per cent of all deaths in men past 50.

This evident increase results from several causes, the principal one being increasing longevity. Life expectancy at birth among the industrial policyholders of the Metropolitan Life Insurance Company rose from 46.6 years in 1911 to almost 67 in 1947. The net result is that two or three times as many men live past the age of 65 as in 1911; this is sufficient to account for the growing numbers of patients who are seen with prostatic cancer. Add to this the fact that education has improved both the physician's ability to recognize the disease and the patient's willingness to consult the physician, and it is unnecessary to postulate a heightened individual susceptibility to cancer.

There is still room for improvement in diagnostic accuracy, because most carcinomas of the prostate gland are discovered only after they have extended

locally or metastasized, that is, too late for cure. Thus, Barringer observed that in only 4.5 per cent of 351 cases was the condition localized within the gland at the time of diagnosis, and Young regarded only 3.4 per cent of 1,000 cases as suitable for curative operation.

Late recognition of the disease is due to an unfortunate combination of circumstances. Moore stated that three fourths of prostatic carcinomas arise in the posterior lamella of the gland. Hinman expressed the belief that a smaller percentage arise there but that most of them do begin in the periphery of the gland. In either case, the majority start at a distance from the urethral lumen and grow slowly, so that the first symptom, usually that of obstruction to urination, appears late in the course of the disorder. Unluckily, these symptoms are identical with those of benign hypertrophy, which most elderly men regard as normal accompaniments of aging. All these facts conspire to send the patient to the physician after local extension or metastasis has occurred. Moreover, early or small cancers may be surrounded or covered by layers of benign hypertrophy and so escape detection. Thus, urologists are confronted by the hard fact that at least 95 per cent of patients have inoperable or unrecognizable lesions, as far as cure is concerned, when they are first seen. While this can be remedied to a considerable extent by making rectal examination part of every routine physical examination (as it should be for other reasons), it has led most urologists to take a dim view of attempts to cure carcinoma of the prostate gland. Thus, both the profession in general and the urologist need more education, if they are to discharge their obligations to these patients.

Since, in existing circumstances, most patients require palliative treatment and since this is bound up with endocrine relationships, these will be reviewed.

It has been firmly established that normal development and maintenance of the prostate require male sex hormone from normal testes, which elaborate it under

the influence of gonadotropins secreted by the anterior lobe of the hypophysis. Castration causes simple atrophy of the normal (not the hypertrophied) prostate and hyperplasia and increased secretory activity of the anterior pituitary. Linked with the endocrine control of the prostate are the phosphatases, enzymes which split phosphoric acid from its esters and which are important in the formation and destruction of bone. The alkaline phosphatases are concerned with many diseases of bone, but the acid phosphatases, while occurring in organs other than the prostate, are of clinical importance only in carcinoma of the prostate. The mature normal prostate has a higher concentration of acid phosphatase than any other organ in the body (Kutscher and Wolbergs). It is elaborated by the acinar epithelium (Gomori) and is abundant in its secretion (Dmochowski). It is present in high concentration in most carcinomas of the prostate and in their metastases (Gutmans and Spröul) and is present in increased concentration in the blood serum of 85 per cent of patients with carcinoma of the prostate which has metastasized to bone (Gutman, Barringer and Woodard, Huggins).

Contemplation of these facts apparently led Huggins in 1939 and 1940 to castrate 20 men with prostatic cancer which had metastasized to bone, on the assumption that, since the normal and the cancerous prostatic cell behave alike with respect to the formation of phosphatase, they might respond alike to castration. Seventy per cent responded favorably, with relief of pain, gain in weight, regression in the local and metastatic lesions and a fall in the acid phosphatase level of the serum. Similar effects followed use of estrogens without castration, and prompt relapse followed administration of male hormone. Spontaneous relapse occurred in most patients after relief varying from a few months to several years and was thought to result from stimulation, by the hyperactive "castrate" anterior pituitary, of the adrenals, which formed androgenic substances. This has not been proved.

Huggins' brilliant study is the basis for most of the effective palliative therapy now in use.

DIAGNOSIS

The history is not helpful unless metastasis to the pelvic bones or local extension of the tumor into pelvic nerve trunks has produced a troublesome sacral backache or pain simulating sciatica. The usual presenting complaint is difficult urination, with nocturia.

The diagnosis depends primarily on recognizing stony induration. At first there is a discrete slightly mobile nodule. Later the whole gland is hard, nodular and fixed by periprostatic extension.

Prostatic tuberculosis may simulate carcinoma, but is ordinarily differentiated by the younger age of the patient, by the story of vesical irritation and urgency without obstruction and by the presence in the urine of pus and tubercle bacilli, with a sterile culture.

The prostatic calculi which do not produce the characteristic crepitus, and which may coexist with carcinoma, are identified by roentgenogram, which will also show metastases to the pelvis when present. Early, there are isolated circumscribed areas of increased density, in which the bony trabeculae are lost; later, these small metastases may coalesce to involve large areas or even whole bones (osteoblastic metastases). In exceptional instances small patches of bone simply disappear (osteoclastic metastases). Confusion is likely to arise chiefly with Paget's disease, in which the

trabeculae are increased in size and density, although there may be a patchy appearance that makes differentiation difficult.

It is here that phosphatase determinations are most helpful. In 85 per cent of metastases to bone from prostatic carcinoma the acid phosphatase will be elevated. Huggins regarded a level between 4 and 10 units (King-Armstrong) as suggestive and levels above 10 units as diagnostic. The alkaline phosphatase is also elevated in metastases from the prostate, but in Paget's disease only the alkaline phosphatase is above the normal level of 12.5 units.

Estrogens may be given to clarify the diagnosis. They are useful when observations based on palpation are inconclusive, particularly if local fixation is present and the phosphatase levels are normal; if the roentgenogram shows lesions of uncertain character or even if the prostatic lesion is obviously localized but the patient is a poor surgical risk, one may then give an estrogen in adequate doses for six to eight weeks, at which time definite regression of the local lesion confirms the diagnosis. If it remains stationary or progresses, it may be noncancerous in the first instance or refractory to estrogens in the second. A metastasis to bone which was only suggestive in appearance originally may, after six to eight weeks of treatment, appear larger, denser and more sharply margined, even if it is destined to disappear later. Failure to change indicates either its nonmalignant character or refractoriness to estrogens.

When the suspected prostatic lesion is discrete and slightly mobile, when there is no evidence of metastasis and when the patient is in good condition, the question of radical perineal prostatectomy arises. Biopsy by aspiration or with the Silverman needle or some punch, such as that of Lowsley, has many advocates but, while adequate in larger lesions, has proved inadequate in my hands because of the difficulty in securing tissue from a small area. My own preference is for perineal exposure of the prostate. If the suspected area is not typical of carcinoma on direct inspection and palpation, it can be excised with surgical diathermy for fast frozen section; if it is typical or if results of biopsy are positive, one should proceed at once with radical removal of the gland.

In some instances Colston has observed that a localized nodule of carcinoma which is adherent to adjacent tissues will regress sufficiently with treatment with estrogens to permit successful radical removal.

While radical perineal prostatectomy is the only method which has yielded bona fide cures in prostatic cancer (56 per cent of five year symptom free survivals by Young and by Colston), many objections to it can be cited, although one does not encounter them in connection with other visceral cancers. The low rate of operability can be improved by a concerted effort. Colston has reported an operability rate of 20 per cent in recent years; Jewett has reported a mortality rate of 3 per cent in patients under 70, and a rate of 10 per cent for men over 70 still compares favorably with that for resections of the stomach or large intestine in similar circumstances. While Kahler has claimed that perineural infiltration outside the prostate is almost always demonstrable, even with small lesions, both Hinman and Young have reported cures as long as seventeen years after operation, which seems to nullify Kahler's claim. The risk of urinary incontinence is not inconsiderable, but can often be corrected; when

the stakes are considered, it does not seem a valid contraindication to the operation. To repeat, it is the only method which has cured any patients.

It should be mentioned that neither the suprapubic nor the retropubic approach gives as good exposure as does the perineal, particularly at the apex of the prostate and the bases of the seminal vesicles.

PALLIATIVE TREATMENT

The employment of palliative measures presupposes that the local lesion has extended or metastasized, that the patient's general condition prevents operation or that stiff hips make the perineal exposure impossible.

Nesbit, Herger and Sauer and others have pointed out that the good effects of endocrine therapy will last only for a limited period (varying from a few months to several years) in the individual patient. This makes it desirable to withhold such treatment until the appearance of pain, for which it is most useful. Its use as a diagnostic measure or in an attempt to make an inoperable lesion operable constitutes a valid exception. For the same reason, it may be preferable to administer estrogens intermittently rather than continuously, stopping the use of them after the symptoms are controlled and restarting when careful follow-up gives evidence of relapse.

Therefore, a patient who has an inoperable carcinoma with few or no symptoms should merely be kept under observation until treatment is demanded by the symptoms and not merely by the knowledge that a cancer is present.

Troublesome obstruction to urination is easily corrected by transurethral resection.

Pain from local extension or metastasis is best treated with endocrine methods. There is no conclusive evidence that castration is superior to estrogens, and I prefer to reserve it for uncooperative or forgetful patients, for those whose severe pain demands prompt relief and for those in whom estrogens are or have become ineffective or impossible to use because of side effects. Huggins, on the other hand, expressed preference for castration, on the grounds that estrogens are less effective, cause soreness in the breasts in many patients and are known to be capable of carcinogenesis. He used the estrogens to combat the hot flashes which follow castration, when operation is refused, as a diagnostic measure and for relapse after castration.

Many estrogens can be used, but diethylstilbestrol and ethinyl estradiol ("estiny") are usually preferred, because of their known potency and because of their effectiveness when given orally. Both may produce tender enlargements of the breasts, nausea, cutaneous eruptions, hemorrhagic diatheses and mental disturbances, although the incidence of troublesome reactions is low. Diethylstilbestrol is said to cause them more often than does ethinyl estradiol. The dosage recommended varies, in the case of diethylstilbestrol, from 0.5 to 40 and for ethinyl estradiol from 0.15 to 2.5 mg. per day. Either preparation is best given in a single dose at bedtime, in the hope that any nausea will occur at night and will be too mild to awaken the patient. I prefer 5 mg. of diethylstilbestrol daily until symptoms are controlled, followed by a gradual downward revision until a maintenance level is found, after which the treatment is interrupted periodically.

Failure or relapse is treated with doses up to 20 mg. or more daily; if these fail, castration is used. Although prospects of success from castration after the use of

estrogens are none too good, an occasional patient will experience striking relief.

The patient who is intolerant of diethylstilbestrol is given a trial of ethinyl estradiol; if this produces side effects, one may implant 40 mg. of alpha estradiol in pellet form subcutaneously at intervals of six to twelve weeks, as recommended by Kearns, before resorting to castration.

Some writers favor various combinations of castration and estrogens, but evidence that this is superior to either one alone is not available.

If pain becomes severe despite these methods or combinations of them, one should not forget the occasional usefulness of roentgen therapy, the subarachnoid injection of alcohol and cordotomy.

Treatment of relapses by irradiation of the pituitary and adrenals, and even by adrenalectomy, has not been successful (Herger and Sauer, Huggins).

RESULTS

Results of palliative therapy are extraordinarily difficult to evaluate concisely, because the best criterion is prolongation of comfortable life, and this is difficult to tabulate. Moreover, no one has yet had time to accumulate any sizeable series of cases followed up for a minimum of five years. In the meantime one can secure some useful information from the death rate of series of patients with and without endocrine therapy for shorter periods.

As a control Nesbit followed up 783 patients treated before 1940 and found that 69.4 per cent had died by the end of the second year after diagnosis. Similar data have been secured from the literature on 569 patients treated by castration, estrogens or both by Vest and Frazier, Greene and Emmett, Nesbit, Herger and Sauer and Huggins. Thirty per cent of these patients had died by the end of the second year, that is, about half the patients who might have died without endocrine therapy were still living. More conclusive data will have to await the passage of time, but Hinman, while recognizing the contribution that the estrogens make to the patient's comfort, expressed doubt that there would be any great net prolongation of life. On the other hand, 5 of Huggins' original 20 patients were living six and one-half to eight years after castration. The series is too small to exclude chance variations, especially since Chwalla observed 2 patients who lived eight and nine years, respectively, after permanent suprapubic cystostomy for prostatic cancer.

Nevertheless, endocrine therapy is affording to many unfortunate old men periods of normal life which simply would not be available without it. Perhaps the most encouraging feature of the whole thing is the prospect that, in the not too distant future, chemical cure of this and other cancers may become a reality.

SUMMARY AND CONCLUSIONS

Carcinoma of the prostate gland has been increasing steadily in frequency during recent years because of increasing longevity with aging of the population.

Prognosis is poor because slow growth leads to late recognition of the disease.

When recognized early, carcinoma of the prostate may be cured in about half the cases.

The chances of cure can be increased only by educating both the patient and the physician.

Palliation by means of endocrine therapy contributes to the comfort of the majority of patients with inoperable lesions.

SPECIAL ARTICLE

CANCER OF KIDNEYS, ADRENALS AND TESTES

GEORGE F. CAHILL, M.D.

NEW YORK

(Continued from page 362 in *The Journal*, October 2)

CANCER OF THE ADRENAL GLAND

The adrenal gland is actually two glands fused together in development. In the human being these are known as the cortex and the medulla. Each has an essentially different origin, a different type of tissue and a separate function, but they happen to be enclosed in one enveloping capsule and tissue stroma.

Tumors of the adrenal gland are not frequent. When they arise they can be basically classified as follows:

1. Tumors derived from the various layers of connective tissue, blood vessels, lymphatics or nerve structures within the gland are of a type that may occur in any gland. They occur rarely in the adrenal. Tumors of these tissues which have been reported as occurring in the adrenal gland are as follows: fibroma, lipoma, neuroma, neurofibroma, myoma, osteoma, hemangioma, sarcoma, lymphangioma and melanoma.

2. Tumors derived from the medulla are peculiar to that tissue and are of the ectodermal sympathetic nervous system. They may be (1) of the basic nerve cell, a sympathicoblastoma, (2) from the sympathetic ganglion, or a ganglioneuroma, or (3) from the pheochromocytes, a pheochromocytoma or a paraganglioma.

3. Tumors originating from the adrenal cortex are mesodermal glandular tumors and cytologically are hyperplasias, adenomas and carcinomas.

FASCIAL TUMORS OF THE ADRENAL GLAND

Tumors arising from the various layers of connective tissue, the blood vessels, lymphatics and nerve structures of the adrenal gland are extremely rare.

The benign tumors, such as fibroma, lipoma, neuroma, neurofibroma, myoma, osteoma and hemangioma, are usually without symptoms unless they become large enough to cause distress from their size. Often they are discovered by accident in examination, an asymptomatic retroperitoneal mass being found in either flank and the diagnosis being made only on operative removal or at autopsy. When the cancers such as sarcoma, lymphosarcoma or melanoma occur the symptoms are those seen with retroperitoneal cancers, some loss of weight, strength and appetite, a gradual anemia and, depending on the extension of the tumor, epigastric or flank distress. As a rule, studies rule out evidence of changes in the gastro-intestinal tract and in other organs and often an indefinite retroperitoneal mass is discernible by roentgen ray or by abdominal palpation. By surgical exploration and biopsy the diagnosis has been established. Usually surgical removal of these infiltrating tumors has been impossible. High voltage roentgen therapy may benefit in those tumors radiosensitive, as certain of the lymphosarcomas. As yet

the effect of the newer therapeutic agents on these rare tumors is unknown. The course in most of these tumors is extension and death. Fortunately they are extremely rare.

TUMORS OF THE ADRENAL MEDULLA

When tumors arise from the adrenal medulla they may be divided clinically into those which do not produce hormones and those which do.

The medulla of the adrenal gland is of the sympathetic nerve system. The primitive nerve cells, the sympathogonia, grow into the hollow of the adrenal cortex so that the cortex extends over and encloses the medulla. The sympathogonia forms two types of cells, one the fibril ganglion cell and the other the secreting endocrine cell.

Sympathoblast Sympathetic ganglion cell	Sympathogonia	Pheochromoblast Pheochromocyte (secreting endocrine cell)
--	---------------	---

Similar ganglion tissue occurs in the retroperitoneal tissues, as the sympathetic ganglions along the aorta and vessels, Zuckerkandl's body, the sacrococcygeal body and the carotid body. Tumors occur in these situations similar to those in the adrenal medulla and may be nonhormonal ganglion cell tumors or hormonal pheochromocytoma cell tumors. The latter have not been reported in the carotid body.

NONHORMONAL TUMORS OF THE ADRENAL MEDULLA

Tumors of the ganglion cell are nonhormonal and occur most often as the extremely malignant immature sympathicoblastomas or less often as the relatively benign neurocytomas of adults.

The immature cell tumors, sympathicoblastomas, occur more frequently in infancy and childhood and the malignancy rates in seriousness with that of the embryomas of Wilms. They occur in either sex, in either adrenal gland or in any of the retroperitoneal sympathetic ganglions. They are seen most often in the first or second years of life and become less frequent as age progresses.

There are usually no symptoms of their presence until profound constitutional changes occur, such as loss of appetite and weakness and anemia, or a tumor mass is accidentally discovered in an enlarging abdomen. There may be loss of weight, but this may be offset by the growth of the tumor mass. At other times it is the presence of metastases that attracts attention to the condition. Long ago, Hutchinson⁶ called attention to the metastases occurring in the orbit and skull or in the left side of the neck from an original tumor which was later found in the left adrenal gland. Similarly, Pepper⁷ reported also finding in infants a tumor of the thorax and the liver occurring secondary to a cancer in the right adrenal gland. In both of these types of tumors, the origin and the cells are the same, adrenal medullary sympathicoblastomas, but the tumors in the right and left glands have different routes of metastases. Most of these cases were unrecognized until metastases had occurred, and this tumor probably in this stage has a complete mortality.

Occasionally such sympathicoblastomas may be recognized before metastases are present. Only by

6. Hutchinson, J.: Left Adrenal Metastasis, *Quart. J. Med.* 1:33, 1907.
7. Pepper: *Am. J. M. Sc.* 121:287, 1901.

careful examination of the abdomen, a mass may be found in such infants with a minimum of symptoms. In such, an increase in size of the abdomen may be noticed by the mother before the mass is detected. When found, it usually is in one of the flanks or

Fig. 5 (R.V.).—A retrograde bilateral pyelogram in an infant girl with a sympathicoblastoma of the left adrenal gland. The tumor mass has pushed the left kidney outward and downward and partially rotated the kidney. The kidney was not involved in the cancer.

sides, and resembles often that seen in Wilms' tumor. It is attached to the posterior part of the peritoneum, usually is soft but may occasionally be hard, projects anteriorly and may be covered by the stomach or intestines. It is without pain or tenderness and may or may not move with inspiration. Excessive handling of the mass is considered to be not without danger of disseminating metastases. When any such mass is present, determination of the origin of the mass is imperative. For this, intravenous or subcutaneous secretory pyelograms have been of great value. Because of the size and age of the infants, secretory pyelograms are, if possible, preferred to retrograde cystoscopy. The diagnosis often is between a renal and an adrenal mass. In the adrenal tumor the films usually show a normal secreting and normal anatomic kidney on that side, often pushed down by the mass above. If so, the greatest odds are that a sympathicoblastoma is present. In a Wilms' tumor of the kidney there is usually diminished secretion on that side due to replacement of renal tissue by tumor growth. There is also distortion and displacement of the renal calyces and of the pelvis by the renal tumor mass. In other words, the adrenal tumor is without the kidney and Wilms' tumor is within. In some cases it may be necessary to do retrograde pyelograms to make a differentiation from a nonsecreting hydronephrosis, or congenital cystic kidney. In some cases, because sympathicoblastomas occasionally invade the kidney, a differential diagnosis is impossible without microscopic section, especially with the retroperitoneal sympathicoblastoma and extrarenal embryoma of Wilms. Surgically it is unnecessary, because the two types require identical therapy. Delineation of these types

of large tumors by perirenal insufflation of air has been found unnecessary, may be dangerous and may make removal more difficult.

There are fewer cancers that have a poorer prognosis than the sympathicoblastomas of infancy, mostly because of failure to recognize the disease while the tumors are small and before metastases.

Avoidance of trauma to the tumor and early removal before metastases offer the only correction. Sympathicoblastomas are considered to be among the radioresistant tumors. Wide transverse transperitoneal approach through the upper part of the abdomen is the method of choice. Since most of these tumors grow anteriorly into the abdomen, opening of the retroperitoneal tissue, ligation of all contributing vessels around the tumor and then removal of the tumor are the accepted steps of the procedure. At times the growths may be closely attached to the cava or aorta, but should be removed in spite of attachments and removed intact because, as stated before, in complete removal before metastases lies the sole possibility of relief.

More rarely than the tumors of infancy, similar tumors of more adult cells occur in older age groups, in both children and adults. They occur in the same places, adrenal medulla, retroperitoneal ganglions, Zuckerkandl's, and the coccygeal body, and also in the carotid. Their malignancy is according to the differentiation and activity of the cells. The usual neurocytoma is much more differentiated than the

Fig. 6 (S.F.).—A retrograde pyelogram in a child with a right sympathicoblastoma of the adrenal gland. This shows the large mass above the right kidney pushing the kidney down and rotating it. The kidney was not involved.

sympathicoblastoma and is much less malignant; in fact some of the adult neurocytomas may be considered benign.

Usually they are symptomless; occasionally they may cause pain because of pressure due to their size. Often they are discovered accidentally on physical examination. When found, they present a rounded moderate soft smooth mass arising from either flank or from the retroperitoneal tissues of the abdomen. They frequently are movable, attached pos-

teriorly and not tender. Metastatic dissemination is uncommon. For diagnostic purposes, intravenous pyelograms may show no change in renal anatomy or physiology except displacement downward by the tumor. Perirenal insufflation of air may show that they arise from the adrenal fascia area but will not differentiate from any other asymptomatic tumor of the adrenal gland. At times, because of their situation, they cannot be told from asymptomatic tumors of the pancreas or from the various fascial tumors of the area, such as leiomyosarcoma or lymphosarcoma.

The therapy of neurocytoma is surgical removal. This is best by the transverse transperitoneal route through the upper part of the abdomen. Removal may be difficult due to size but usually is not, because they are definitely encapsulated, with no close attachments to organs, and have not the expanded multiple circulatory systems seen with the more malignant carcinomas. Often after complete removal of the tumor there is no recurrence, because of rarity of metastasis.

Cytologically these tumors are graded according to the age of the sympathetic cells and their activity. In extremely young infants the large soft rapidly growing tumor shows sheets of undifferentiated sympathogonia cells with bizarre shapes and many mitoses and with cell disorder. Necrosis in these tumors is frequent. The older more differentiated tumors uniformly show more cells approaching the adult fibril ganglion cell and with more orderly arrangement of the cells and rare mitotic division.

HORMONAL TUMORS OF THE ADRENAL MEDULLA

Tumors of the hormonal pheochromocytoma cells of the adrenal gland are rare but because of interest in the phenomena they are more often diagnosed and reported, and they appear to be more frequent than formerly suspected. The typical syndrome when first described by Labbe and Tinel Doumer⁸ was called "paroxysmal hypertension."

The pheochromocytomas are tumors of the secreting endocrine cell of the sympathetic system. They occur in the adrenal medulla most frequently, but also occur in other pheochromocytoma tissue such as the retroperitoneal ganglions, sacrococcygeal body and intrathoracic ganglions. They may be multiple in several ganglions; usually two only have been reported as occurring at a time. The multiplicity has been estimated as to occur in 10 per cent of the cases. MacKeith⁹ stated that 9.7 per cent were bilateral and 9 per cent were cancerous.

The secretion from the cells of these tumors causing the syndrome is considered to be an excess production and use of the pressor substance, epinephrine. The symptoms and changes in the metabolism and vascular system are the result of the intermittent or continuous secretion of epinephrine. It has been shown to be in excess during an attack, directly, by Beer, King and Prinzmetal,¹⁰ and, indirectly, by Goldenberg, Snyder and Aranow.¹¹

When the tumor occurs the usual symptom com-

plex is seen, which has previously been described as paroxysmal hypertension. This effect has been accepted as a temporary release of an excessive amount of pressor substance into the blood. The reaction of the patient is to this excessive amount of pressor substance. More recently it has been shown by Palmer and Castleman,¹² by Howard and

Fig. 7 (J.L.).—Air insufflation roentgenogram in a case of pheochromocytoma of the left adrenal gland. The area of the right adrenal gland is normal and the wedge-shaped normal gland is visualized. On the left side the ovoid-shaped gland is shown about four to five times the size of a normal adrenal gland.

Barker,¹³ by Quinby¹⁴ and others that with continued growth of the tumor a continuous sustained hypertension may follow the intermittent hypertension so that a symptomatic picture may be present that in time may resemble the so-called essential hypertension.

The tumor and its syndrome occur more frequently in young or middle adult life. It may occur in children. It is rare in old age. It has been described in both sexes but is much more frequently seen in women.

The usual symptom complex of paroxysmal hypertension may occur either spontaneously or may be induced. Usually the symptoms are brought about by emotional crises or sudden physical activity. In the same person the symptoms are usually similar each time they occur. They start often with a pronounced beating of the heart, a pounding headache, epigastric distress or pain and often a sense of constriction of the hands and feet. The attack is emotionally disturbing and may be associated with a sense of impending death; it may last for a few minutes to several hours. With the ending of the attack, excessive perspiration occurs, with exhaustion and fatigue, and if the attack lasts long or is severe it may be followed by shock. After the attack there may be cutaneous dilation of the blood vessels of the hands and feet, which are cold, at times blanched, during the attack. Associated with the attack is a definite rise in both systolic and diastolic blood pressure and a subsequent fall to normal or a lower level on its ter-

mination. Examinations of blood and urine during and for a while after the attack show sugar curves similar to those seen with diabetes mellitus. This is more often seen in adults and older persons and less frequently seen in children. At times death may occur during or after an attack, most often associated with pulmonary edema.

In some cases a more sustained and continuous hypertension may result as the disease progresses, so that the symptoms may be confused with "essential hypertension." When such occurs, vascular changes may result and may remain permanent even though the tumor is removed. These vascular changes may be present in the eye grounds. The type of vascular changes in the eye grounds occurring in the cases in children has been reported by Bruce¹⁵ to be specific to the condition and not seen by him in other hypertensive conditions.

The diagnosis of pheochromocytoma depends on (1) a history of typical attacks and associated clinical findings; (2) evidence in so-called essential hypertension of the symptomatic and clinical findings in the pheochromocytoma syndrome; (3) demonstration in the blood during the attack of a pressor substance as shown by Beer, King and Prinzmetal¹⁶ or, more easily, a significant reduction in the blood pressure by the intravenous introduction of an epinephrine antagonist, such as the benzodioxane series as described by Goldenberg, Snyder and Aranow¹⁷; (4) precipitation of an attack in the resting stage by an epinephrine-producing stimulus such as histamine, as described by Roth and Kvale,¹⁸ and (5) roentgenographic evidence in a case with the syndrome of the presence of the tumor, without or with perirenal insufflation of air or by renal displacement as shown through the use of films with pyelographic mediums.

A number of metabolic changes have been found with these tumors. The differentiation between hyperthyroidism and pheochromocytoma by symptoms is sometimes difficult. Concomitant swelling of the thyroid with tumor and syndrome has been described by Bauer and Belt.¹⁷ Elevation of the serum potassium and increased urea clearance have been found. The glycosuria present may confuse the diagnosis, but it is usually resistant to the ordinary treatment of diabetes mellitus. The sugar changes, as before stated, are greater in older persons. Hysteria and psychoneurosis may present difficulties in diagnosis.

Recent operative reports show a decided lowering of the mortality in the surgical therapy of these tumors. The only known cure is removal. The use of tribromoethanol in anesthesia induction has usually avoided the precipitation of an attack. Because of their situation and the possibility of multiplicity, the transperitoneal approach has been used most frequently. In the removal of these tumors danger lies in their handling during the operation. Experience has shown that all vessels to and from the tumor should be ligated before the tumor is handled. Handling of the tumor without vascular separation has been shown in some cases to be immediately followed by death, from release of a

fatal excess of epinephrine. When the tumor is successfully removed, there is an immediate fall of blood pressure. This at first may require administration of epinephrine but usually shortly afterward returns to normal levels. In some cases the return is slow and accompanied by lethargy. After removal there is usually no mortality and cure results. Cases have occurred in which symptoms have persisted after removal of a tumor. This has usually been due to the presence of another unrecognized tumor, which is another reason for complete transperitoneal examination of the abdomen, because by far most of these tumors are intra-abdominal. Rarely, because of vascular difficulties or vascular attachments, a tumor may be incompletely removed. Not infrequently the persistence of the symptoms is due to functioning metastases. There are no known clinical means for determining whether the lesion is benign or cancerous either before operation or at operation, except by noting extension of the tumor through its capsule and local invasion—the usual extension of these tumors, because death most often intervenes before widespread metastases occur.

These tumors cytologically show excess of pheochromocytoma cells with increase of interstitial stroma and ganglion cells. The hormonal activity of these cells can be determined by biologic assay or by demonstrating the amount of hormonal material in the cells by special stains. Malignancy is determined by the cell structure and by the cell invasion through the stroma and capsule.

TUMORS OF THE ADRENAL CORTEX

Tumors of the adrenal cortex are classified as follows¹⁸: (1) tumors with no recognizable hormonal changes in the patient; (2) tumors with changes due to hormonal influence on the secondary sex characters (adrenogenital); (3) tumors with changes due to hormonal influence on various metabolic processes (adrenometabolic tumors) (Cushing's syndrome), and (4) tumors with changes due to various hormonal influences, both of the adrenogenital type and the Cushing syndrome of the adrenometabolic type (a mixed syndrome).

Nonhormonal Tumors Of Adrenal Cortex.—The nonhormonal tumors are not infrequent. They have occurred mostly in adults, usually over 30 and more often in the later decades, and have been seen in both sexes. They are usually silent. When recognized, they have usually been present for a considerable time. At first without any symptoms, they may later cause a deep pain in the abdomen or pain in the flank on the side in which the tumor is present. Often they are studied by roentgen examination of the gastrointestinal tract without discovery. Later, with increasing size of the tumor, a mass is found on the affected side. The deep location of the adrenal gland and the slow growth of the tumor and its slowness of invasion of adjacent viscera often allow the tumor to grow extremely large before it is discovered. The pain occurring may be abdominal and in the flank or both and is usually made worse by activity. There are frequently some loss of weight, fatigue and diminution of appetite, and mild anemia may be present. These tumors are not tender. Not infrequently, at

the time of the first recognition of the tumor, pulmonary metastases may be demonstrated by thoracic roentgenograms. In others, in spite of the extraordinarily large size of the tumor, no metastases seem to occur.

When examined by roentgen rays, especially with pyelographic studies, these tumors usually show a mass in the flank above the kidney and displacing it downward on that side. At times the tumor may project anterior to the kidney, and its outline may be demonstrated by the shadows of other viscera. If the tumor is small it may be necessary to demonstrate its presence by perirenal insufflation of air. If the tumor is large and freely palpable such a procedure may not be necessary. Some of these tumors have occurred in accessory adrenal glands, either in the prerenal area, where they have been

Fig. 8 (A.M.).—A retrograde pyelogram of a case of a large carcinoma of the left adrenal gland, without any hormonal symptoms. The large dense shadow of the tumor is seen above; it has pushed the kidney down and turned it so that it is visualized as if it were seen with the lower pole anterior and the upper pole posterior.

confused with tumors of the tail of the pancreas, or in the broad ligament of the pelvis, where they have been taken for ovarian or other pelvic tumors. Most of these tumors, although definitely encapsulated, are malignant, and because of their silence and large growth the prognosis is sometimes poor. The tumors are often irregular in shape, may be nodular and may vary within the tumor from dense hard areas to softer areas, often necrotic. They are yellowish and resemble the clear cell hypernephroma of the kidney in gross appearance. On microscopic section they show cells of bizarre shapes and sizes and arrangements. In some of these tumors the cells are of tremendous size; the largest cells occurring in the human body have been seen in these tumors. Only rarely are cells with vacuoles containing steroids seen in this type.

The accepted therapy is complete removal of these tumors, usually through a transverse or oblique anterior transperitoneal approach. After the posterior peritoneum fascial planes are opened the viscera anterior to the tumor are usually displaced downward and inward, and after the vessels to the

tumor are ligated they usually are removed easily in spite of their huge size, because of their encapsulation. Recovery from removal is the rule, and as numbers of these patients have apparently no metastases, freedom from extension or recurrence often occurs.

Hormonal Tumors of Adrenal Cortex.—Tumors with

Fig. 9 (S.S.).—An air insufflation roentgenogram in a case of carcinoma of the left adrenal gland in a male without hormonal symptoms. The rounded denser shadow shows the adrenal gland growing down in front of the kidney, which can be visualized through the tumor because of the air, which also surrounds the kidney within Gerota's fascia.

changes due to hormonal influence on the secondary sex characters are divided into: (a) changes due to excess androgens (1) in a girl toward adult masculinity, (2) in a boy toward adult masculinity; (b) changes due to excess estrogens (1) in a man toward femininity.

Tumors with Symptoms Due to Excess Androgens: In a girl toward adult masculinity. When the disease occurs at birth or in early childhood the symptoms have been described as pseudohermaphroditism. The changes of male character due to excess hormonal secretion are not infrequent in girls, but tumor as a cause is rare. The most frequent cause of the changes is bilateral adrenal hypertrophy. With the exception of survival time there is often no difference between the symptoms of bilateral adrenal hypertrophy and unilateral tumor. Both begin with hypertrophy of the clitoris, appearance of hair on the genitals, excessive bodily growth for a while, increase in musculature, deepening of voice, accelerated epiphyseal and dental development and often a higher mental aptitude for their age. Acne is often present. There is often a decrease in size of the vagina and other female characters. The children are at times aggressive and combative like boys. Some, on the other hand, acquire a shut-in personality.

When the symptoms are due to tumor, the tumor may be adenoma or carcinoma. The tumors are most often unilateral, and are well shown with roentgenograms taken after insufflation of air. The urine contains androgens far in excess of their age. These androgens are now registered by the amount of 17-ketosteroids excreted in the urine. Very high excretion of 17-ketosteroids has been described as due only to carcinoma, but recently similar high excretions have occurred with bilateral adrenal hypertrophy.

The older prepuberty girls with the syndrome do not menstruate even though the period of puberty has been reached. Rarely a fleeting menstruation has been reported. With the older children a more general hirsutism is apt to develop on face, lips, chest and back, and acne is usually present. In these children the voice may be surprisingly deep. A rapid transitory growth of the child is often followed by a closure of the epiphyses, and if the child recovers from the disease, relative shortness in stature may be the result.

Fig. 10 (M.H.).—An air insufflation roentgenogram of a girl with male puberty symptoms, due to a large cancer of the right adrenal gland. The air infiltrated around the left adrenal gland but poorly around the right, which is shown as the dense mass round in shape above the area of the right kidney.

Tumors in a woman causing changes toward adult masculinity. In the woman after puberty and before menopause there occurs what is called the adrenogenital syndrome. According to Wintersteiner¹⁹ this in its broadest sense comprises all conditions in which the abnormal changes in the sexual sphere are referable to organic or functional disturbances in the adrenal cortex. In these women it consists of the appearance of male secondary sex characteristics and the suppression of female characteristics and function. When the syndrome becomes established after puberty or later in life, the first change noted is the appearance of hair on face and body of male type; this, called hirsutism, is followed by irregularity or cessation of the menses, changes in body contour and enlargement of the clitoris. Such syndromes are not infrequent. In many clinics women appear with some or all of the symptoms, seeking a change back to normal. From studies made on these patients, tumor of the adrenal gland is not a frequent cause of the change. Normal anatomic or hypertrophied adrenal glands are usually noted. When tumor does occur, however, the symptoms are clearcut. The hair definitely has an acceleration of growth; when menses cease the cessation is complete. Headaches at the time of menses are frequent with tumor. Acne is present and may be pronounced; clitoral hypertrophy is evident, and the younger the patient the more pronounced is the change. Deepening of the voice, and recession of breasts, labia, uterus and sexual desire often follow. Associated with these changes are the appearance of excess amounts of androgens

in the urine. These are now determined by the estimation of the 17-ketosteroids, and with tumor these have been high in these cases, over 100 mg. per liter.

It is in this type of case that the roentgenograms taken after insufflation of air have been most helpful in the diagnosis. The clear fascial planes in these cases allow the air to infiltrate easily and outline the adrenal glands and tumor, if present, extremely clearly.

When tumor is present in these females, both children and adults, surgical removal is indicated. It may be done through the flank or preferably transperitoneally. Removal of these tumors is not difficult and is usually free from complications of adrenal failure. Recovery is rapid and the regression of the male characteristics occurs with the restoration of those of the female. Menses often return in a month or so and the excess hair sheds most profusely at the menstrual periods. Most of these tumors have been adenoma or adenocarcinomas and the cells have acidophilic granules in the cytoplasm, and some have steroid vacuoles. The excess of granular cell cytoplasm has given the name of "granular cell tumors" to this group.

In a boy toward adult masculinity. The usual symptom described in the class has been precocious puberty (*pubertas praecox*). Precocious puberty by itself is not infrequently seen with many causes. Adrenal tumor is a rare cause, much less frequent than similar tumors in girls.

Fig. 11 (F.H.).—An air insufflation roentgenogram of a boy with precocious male puberty. The round outline of the adrenal tumor is shown between the spleen above and the kidney below. This was a "granular cell" tumor.

When tumor occurs there is an increase in size of penis and scrotum without corresponding increase in size of the testes. Hair appears on the pubis and may appear on the face. The child shows increased growth, muscularity and dentition, and advanced epiphysial changes can be seen roentgenologically. The growth may be of the infant Hercules type. The child is often aggressive and unruly and may show postpubertal changes with masturbation and sometimes ejaculations. There

19. Wintersteiner, O.: Adrenogenital Syndrome, *J. A. M. A.* 116: 2587, (June 14) 1941.

is a decided increase of androgen output in the urine as shown by the estimation of the 17-keto-steroids

In these cases the roentgenograms after insufflation of air have again clearly shown the adrenal status, especially presence or absence of a tumor. If a tumor is present, operative removal is indicated. Some of these boys have shown mixed syndromes suggestive of excess of other metabolic hormones besides the androgenic. These syndromes, such as obesity and redness of face with hemoconcentration, would require adrenal substitution therapy during and after removal of the tumor, because such metabolic syndromes are often associated with atrophy of the opposite adrenal gland and substitution therapy may be necessary until the opposite adrenal gland resumes secretion.

Some of the tumors have been adenomas and others adenocarcinomas. Like the tumors in females they have cells with acidophilic granules in large numbers if only the adrenal-sex syndrome is present, but if obesity and other signs of Cushing's type are present there will be found large numbers of foam cells, cells with multiple steroid droplets in the cytoplasm.

When the tumor has been successfully removed in these cases there is a recession of the child's precocious puberty and the child resumes a normal course of life. The fixed changes in the epiphyses do not regress.

Tumors With Symptoms Due To Excess Estrogens.—

Tumors with symptoms due to excess estrogens are rare, producing changes in a man toward femininity. The usual symptoms are decrease in size of the penis, enlargement of the breasts and nipples, loss of sexual desire and impotence. The symptoms have been progressive in the few rare cases in which the disease occurred and then with loss of weight, anemia and emaciation; a tumor mass was found in the abdomen as the cause. Levy-Simpson and Joll²⁰ showed in 1 of these cases that the effect on the patient was the result of excess estrogens elaborated by the adrenal tumor. The excess estrogens disappeared from the urine on the removal of the tumor, with disappearance of the symptoms. After a time the symptoms reappeared with reappearance of excess estrogens in the urine, when multiple metastases appeared in the lungs and liver before death. The few reported cases have been mostly carcinoma of the adrenal gland and all have been fatal. Fortunately, because of the unique syndrome autopsy studies have been thoroughly made in these few cases.

Tumors with Syndrome Due To Hormonal Influences on Various Metabolic Processes: (Cushing's Syndrome) The syndrome which was described by Cushing,²¹ who suggested that it might occur with basophilic adenoma of the pituitary, was also recognized by Achard and Thiers²² in their "diabetes of bearded women." Cushing, however, outlined a clinical picture in either male or female, consisting of a rapid plethoric painful obesity affecting primarily the face, neck and abdomen but usually sparing the extremities, this giving rise to

an obesity described as the "buffalo type." The facial changes made the eyes appear small and slitlike, like those of pigs, and the picture is called "moonface." There was acrocyanosis with purplish linear atrophy on the lower part of the abdomen and the thighs. Hirsuties might be present. There was a tendency toward polycythemia and some hypertension, and glycosuria were of frequent occurrence. With the syndrome came muscular weakness and porosis of the bones, causing a cervicodorsal stoop and a shortening of the stature. Amenorrhea was present in the women and impotence in the men. There was a definite susceptibility to infectious processes and to physical stress. Mental changes were present and in some, well developed psychoses occurred. Much discussion has occurred as to the cause of Cushing's syndrome. It has been definitely shown that it may be caused by adrenal tumor and that, if the tumor was removed and the patient survived the acute adrenal depletion following, the syndrome described by Cushing gradually disappeared and the patient returned to normal health.

Fig. 12 (H.P.).—An air insufflation roentgenogram of a woman with Cushing's syndrome due to tumor of the right adrenal gland. The ovoid tumor is clearly seen in the outer part of Gerota's fascia above the right kidney. This was a "foam cell" tumor.

Albright²³ from his study stated that the Cushing syndrome is a definite opposite syndrome from the adrenogenital syndrome, the first due to excess production of the S hormone and the latter to excess production of the N hormone. All patients with Cushing's syndrome suffer from an hyperadrenocorticism. The complicated metabolic changes which vary in all patients suffering from the disease make a standard impossible.

The syndrome is most frequently seen in women, less so in men, and it occurs rarely in children. The most frequent adrenal change found associated with the syndrome is bilateral adrenal hypertrophy with microscopic section showing changes known as "foam cell adrenals." Tumor of the adrenal gland occurs as a cause less frequently. The tumors are usually adenomas; rarely is carcinoma found as a cause of true metabolic syndromes. When the syndrome occurs the diagnosis may be made by roentgenograms of the adrenal gland after insufflation of air or by bilateral exploration. Operative removal of these tumors may be followed by acute adrenal deficiency and death if the opposite adrenal

gland is in a nonfunctioning state due to the excess hormones of the tumor. Administration of a potent hormone substance in sufficient amount until the nonfunctioning adrenal gland has resumed its normal role in metabolism is the therapeutic step for correction of the acute Addisonian crisis.

Tumors with Changes Due to Hormonal Influence on the Secondary Sex Characters and on Other Metabolic Processes: A clinical case of mixed syndrome is sometimes seen as often as the Cushing type. The most frequent adrenal cause has been bilateral adrenal hypertrophy. It has been caused by tumor, and a high proportion of these tumors have been carcinoma. It occurs more frequently

Fig. 13 (L.F.).—An air insufflation roentgenogram in a case of carcinoma of the right adrenal gland with "mixed" syndromes. The outline of the tumor can be seen above the right kidney. The tumor was globular and compressed tightly against the liver. The cells of this tumor were both granular and foam cells.

in the female in an older age group but has occurred in both male and female children.

When the syndrome occurs in women with carcinoma, the sexual changes are not as great as in Cushing's syndrome. The diagnosis of 3 such cases in the Squier Clinic was made by the symptoms and the roentgenograms after insufflation of air. Operative removal of the tumors in these cases was followed by acute adrenal deficiency. In one of the cases recovery was undoubtedly due to metastases functioning subsequent to removal of the adrenal tumor. In the 3 cases of this group at that clinic, microscopic section showed all to be carcinoma of both cells with granular cytoplasm and with foam cells.

CANCER OF THE TESTIS

Testicular tumors are not infrequently observed in urologic practice. Eighty-two cases were noted in over 27,000 admissions to the Squier Clinic, and Young²⁴ reported the finding of 25 tumors among 12,000 admissions at the Brady Clinic. Tanner²⁵ estimated that this type of tumor occurred once in every 2,000 hospital admissions. Hinman²⁶ reported that it occurred among 0.063 per cent of male patients admitted to the hospital. It made up about 0.57 per cent of all tumors. Dean²⁷ stated that testicular tumors represent 1.008 per cent of all tumors of both sexes and that 2.09 per cent of all

malignant tumors of males were primary in the testis. The right side seems to be slightly more involved than the left. Bilateral involvement occurs, simultaneous or subsequently; the tumors are rare and are more frequent in cryptorchids.

It has been stated, and it appears to be supported by study, that tumor is more frequent in undescended testes than in normal testes. Incidence of tumors in undescended testes varies from 8.4 per cent reported by Higgins and Buchert²⁸ to 14.29 per cent reported by Dean.

The tumors occur most often in the period of maximum sexual activity. They may occur in infancy, usually as a teratoid, or may occur in old age, more often as a seminoma.

A history of trauma may be elicited in many cases of testicular tumors. The frequency varies from 10 to 30 per cent, according to the author (Cairns,²⁹ Dean,²⁷ Smith,³⁰ Higgins and Buchert²⁸). The fact that the testis is an exposed organ and that even trivial injuries are painful and more apt to be remembered by the patient may contribute to the large incidence of trauma that is in the literature.

Over the last forty years there have been many divergent pathologic classifications of testicular tumors. New growths may arise from any type

Fig. 14.—A plain roentgenogram of the abdomen in a case of carcinoma of the left testis and a metastases in the left lumbar glands giving a bulge shadow to the upper part of the edge of the left psoas muscle. A case suitable only for external radiation.

of cell in the testis. Adami³¹ best described the testicular cell itself as a tripotent cell which has the power to give rise to every order of cell in the body. Thus tumors may occur from any of the three germinal layers, the epiblast, mesoblast and hypoblast. The majority seems to be of two main types, the seminoma tumor from the seminal cell and those of teratoid or embryonal origin. A classification used by Friedman and Moore³² may be suggested because it is simple: (1) seminoma (germinoma), (2) embryonal carcinoma, (2a) chorioepithelioma, (3) teratoma and (4) teratocarcinoma. According to Friedman and Moore, over 96 per cent of the 922 tumors of the testis seen by them in

the Army Institute of Pathology fell into these categories. Whatever classification is used or whatever interpretation is made about testicular tumors it should be understood that pathologists and clinicians agree that for all practical purposes all tumors of the testis are to be regarded as cancerous.

The common tumors of the testicle more often form metastases by way of the lymphatics. The

Fig. 15.—An intravenous pyelogram in a case of a small carcinoma of the right testicle. Hydronephrosis of the right kidney and the outline of the metastases overlying the right renal vessels and causing the hydronephrosis may be seen. A case suitable only for external radiation.

teratogenous tumors are thought to metastasize earlier than the seminomas. The metastases of both at times may be early but more often the tumor may be present for a considerable period without metastases. Metastases do occur by way of the blood stream but much less frequently and may give rise to general metastases without involvement of the primary lymphatics.

The primary lymphatics of the testicles drain along with the spermatic vessels, cross the ureter and empty in the lateral lumbar nodes. These lie lateral to, around and in front of the large vessels below the renal vessels. The chain of nodes extends from the common iliac artery to the renal vessels. The secondary lymphatics drain into (1) the primary nodes of the opposite side and (2) nodes behind and between the great vessels above and below the renal veins. Extension from these glands may be to and through the mediastinum and to the supraclavicular group.

Involvement of the lungs may occur by lymphatics or by the blood stream, appearing as round masses, denser than normal lung tissue, and scattered throughout the lungs. Metastases may occur generally in the liver, facial bones, intracranially and in various places. Metastases in many cases must be late because the enlargement of the testis has often been noted for years. Testicular tumors rarely break through their fascial coverings and invade the scrotum. Extension to the scrotum has been seen with exploratory puncture or ill advised incision into the tumor. Only when these unusual fascial invasions occur does one see involvement of the inguinal nodes, or rarely these nodes are involved late by retrograde flow after the retro-

peritoneal nodes are blocked with tumor infiltration.

Seminomas.—Roughly one third (35 per cent) of the tumors reported by Friedman and Moore were seminomas. This was from a group of patients mostly between 19 and 39 years of age. From all age groups, Cabot and Berkson³³ stated that seminoma occurred in 59 per cent of proved testicular tumors. Similar figures were reported by Geist and Thalheimer,³⁴ by Herman³⁵ and by Nash and Leddy.³⁶ It is of record that seminoma occurs more frequently with increasing age.

These tumors are grossly round or ovoid, elastic, with uniform appearance and heavy to feel. The microscopic appearance is of mostly uniform size rounded monocellular elements with clear cytoplasm. These cells are considered to arise only from the seminal cells. The cells are remarkably uniform and are usually in masses or cords divided by trabeculae of connective tissue. There may be lymphocytic infiltration of this connective tissue, and foci of coagulation necrosis are frequently encountered in these tumors. Occasionally variations of structure occur, so that about 4 per cent of the

Fig. 16.—An intravenous pyelogram in a case of carcinoma of the left testicle, with a large palpable left epigastric mass of metastases that displace the left kidney laterally and obstruct it. This case is suitable only for external radiation.

tumors will have some embryonal carcinomatous tissue. Seminomas usually do not invade or destroy tissue planes or adjacent structures and scrotal invasion is rare.

Embryonal Carcinoma.—Embryonal carcinoma shows considerably more variation in its cell components. The cells are of various shapes, and frequently glandular or papillary structures are present. These tumors are often of undifferentiated cells and appear as solid sheets of anaplastic cells with large and bizarre nuclei. Syncytial cell masses may be seen. Some have frankly teratoid structures, such as the embryo masses of Melicow.³⁷

37. Melicow, M. M.: *Embryoma of Testis*, J. Urol. 44: 333, 1940.

Choriocarcinoma.—Choriocarcinomas have two cellular components and in their arrangement tend to duplicate the placental villi. The two groups are a mass of compact cells with giant multinucleated cells at the borders of these masses. A complete choriocarcinoma is rare. Focal choriocarcinoma occur in about 12 per cent of embryonal carcinomas and teratocarcinomas. Gynecomastia and changes in the endocrine glands occur in cases of choriocarcinoma by itself and in the cases of focal choriocarcinoma.

Teratomas.—Epithelial masses, glands and cysts in association with some undifferentiated tissue and specialized structures such as cartilage or bone make up the usual character of the teratomas. Rarely are teeth and hair present in these tumors. The tissue seen is mostly of differentiated adult type.

Teratocarcinoma.—Teratocarcinomas are a large group of testicular tumors in which differentiated teratoid structures are present with histologically cancerous elements of embryonal carcinomas and choriocarcinomas. Less often will there be semi-nomatous components present.

CLINICAL FEATURES OF TESTICULAR TUMORS

The subjective symptoms of testicular tumors either may be nonexistent or may vary according to the interpretation of the patient. In most cases the presenting sign is enlargement of the testis. Usually the duration of the enlargement may not be known. If the tumor occurs in an undescended testis the first presenting sign may be a mass metastasis. The tumor mass usually is without pain or tenderness. A dragging or uncomfortable feeling is as far as pain goes. Some patients definitely state that the testis feels heavier than it should. At times an associated hydrocele may be present, fluid from which is bloody. Some complain of an abdominal mass in addition to scrotal enlargement. Others may have fixed pain in the back and unrecognized testicular change. Enlargement of the breasts may occur without recognition of change in scrotal contents. All in all there is no definite group of symptoms, most patients coming for consultation because of simple enlargement of the scrotum.

DIAGNOSIS

All enlargements of the scrotum form a group among which tumor of the testis must be recognized. Tumor of the testis involves the testis only. It may be smooth and it may be irregular and nodular. It usually has some areas of rather decided hardness and is much heavier than fluid or normal tissue of the same size. The heaviness of testicular tumor is a characteristic of this particular neoplasm. It is movable in the scrotum, rarely fixing itself to its coverings or the scrotum. The mass is rarely tender, has no feeling of heat and shows no change in the color of the skin. Enlargement of the scrotal veins may be present. The vas is usually normal. Puncture biopsy for diagnosis is not recommended in these tumors.

Tumor of the testis must be differentiated from (1) tuberculosis, (2) syphilis, (3) hydrocele and (4) spermatocele. 1. Tuberculosis almost always involves the epididymis, either head, body or tail. It usually is not painful but may be so and may be somewhat tender. The involved area often fixes itself to the surrounding tissues and may cause a surface area of redness, may cause edema and may

form a sinus. Beading or induration of the vas may occur, as well as nodules in the seminal vesicles or the prostate. Tubercle bacilli may be found in the seminal fluid, rarely in the urine itself. 2. Two forms of syphilis are seen, one a small fibrous testis, practically never mistaken for tumor and the other a large gumma, which is frequently mistaken for a tumor. A positive serum reaction is evidence of syphilis and a blood test should be a necessary step in all cases of scrotal masses suggestive of tumor. Tumor of the testis may occur in persons having syphilis and with positive serums. If a supposed gumma does not rapidly resolve under active antisyphilitic treatment, it should be considered as a tumor of the testis. 3. Hydrocele occurs frequently by itself. It may be associated with tumor and the tumor may be discovered after the fluid is removed. Some hydroceles with thick opaque sacs, containing cholesterol plaques, at times make a differentiation difficult. 4. Spermatocele or cysts usually arise from the epididymis. They are round, elastic and not heavy and frequently can be transilluminated.

THE HORMONE TESTS IN DIAGNOSIS

The demonstration of a gonadotropic hormone in the urine of patients was first described by Zondek.³⁸ At first considered a reliable test, experience has shown that the amount of gonadotropic hormone with testicular tumors is determined by the amount and activity of syncytial secreting cells within the tumor. When properly performed and interpreted the test is dependable and valuable. The reaction is usually negative (less than 300 mouse units) in seminoma and negative in adult teratoma. It is positive in various stages in the teratocarcinomas and embryonal carcinomas and ranges from 500 to 10,000 mouse units, depending on the amount of syncytial tissue present. Its most valuable use is in presenting the diagnosis of choriocarcinoma in which secretions of 10,000 to over 150,000 mouse units have been recorded. A reaction to the test with gonadotropic hormone is of no value in determining cancer. A high positive reaction is conclusive of choriocarcinoma. At present the presence of hormone excreted in the urine with a testicular tumor (1) shows the presence of hormonal secreting cells and (2) may show the amount of secretory activity of the cells in tumors such as choriocarcinoma or the cellular bulk present in the less actively secreting teratomas. Thus the presence of a large amount of hormonal excretion with a small testicular tumor would imply an actively secreting tumor or many metastatic secreting cells elsewhere than the primary tumor. If no metastases are demonstrable it would be more probably from the primary tumor, probably a choriocarcinoma. By itself the presence of the hormone is no criterion for determining whether metastases are present. After the primary tumor is removed an abnormal hormonal secretion is evidence that secretory metastatic cells are present somewhere else. The presence of high hormonal secretion may show itself clinically by gynecomastia, either enlargement of nipples or breasts or both.

38. Zondek, B.: *--- und Hypophysenvorderlappenhormone, Klin. in the Diagnosis of* *Gonadotropic Hormone* M. A. 108:607, (Feb. 20) 1937.

TREATMENT

Before any treatment is undertaken in testicular tumors it is essential to determine whether metastases are present. To demonstrate these a number of means are at hand. Supraclavicular (Virchow's) metastases are palpable and should be carefully looked for. Roentgenograms of the chest, preferably stereoscopic films, will show metastases to blood vessels and lung or mediastinal lymphatic masses. Retroperitoneal metastases usually are in the epigastric or hypochondriac area of the side involved. If large they may be palpable. Since the lymphatics of the testes run in the same fascial plane as the ureter and cross it and since the lymphatics near the edge of the psoas muscle or in the preaortic area may be and often are involved, some of these planes and tissues may be outlined roentgenographically. Changes of shape of the edge of the psoas and deflections of the ureter or renal pelvis can be shown by an intravenous urogram, and when present with testicular tumor are usually due to metastases. At times with intravenous pyelograms a deflection of the kidney may be noticed. Occasionally the ureter may become involved by tumor and show by obstruction to the ureter at that level on the pyelogram. It is regrettable, but a considerable number of cases show evidence of metastases when first seen.

If no metastases are demonstrable then surgical treatment may be considered. Simple orchidectomy offers a cure in the rare noncancerous adult teratomas. It may also cure an early cancer that as yet has no extension to the lymphatics. It may also offer a positive pathologic type of diagnosis in cases of suspected metastases to determine the amount and course of roentgen ray therapy. It is the prevailing surgical procedure of large numbers of surgeons, who remove the testicle complete with its coverings through a high inguinal incision with division and ligation of the cord as the primary steps before the handling of the tumor. After removal of the testis and with healing and recovery, roentgen therapy is or is not given, depending on the tumor, the therapist and the patient.

There is a number of surgeons who believe that a removal of the lymph nodes of the lumbar and preaortic area with the fascial planes of the spermatic vessels should be done at the same time as the removal of the testis. This is recommended only if no demonstrable masses are present. In numbers of these so removed, microscopic metastases have been demonstrated. The extension of the operation from a simple orchidectomy to this "radical orchidectomy" in the hands of its proponents has not led to any increase in the operative mortality and has given a greater percentage of freedom from recurrence than any other method. It is not at all suitable in the presence of demonstrable metastases, especially if they are without the area possible of removal. Study has shown that in autopsy in terminal cases there are widespread metastases but that the routes of these in early cases is often through lymph channels not difficult to extirpate sufficiently. The operation is especially of value in the early teratocarcinomas or mixed tumors because of their well recognized resistance to roentgen therapy. Although seminomas are radiosensitive, surgical removal of early seminomas by radical removal is preferable because their slower

growth, their remaining stabilized in nodes for some time and lack of infiltration make removal of these nodes not difficult.

ROENTGEN THERAPY

As in the case of the pathologic and other classifications of testicular tumors, a classification of the methods of radiotherapy for these testicular tumors is difficult. For a while there seemed to be as many radiologic technics for treating testicular tumors as there were radiologists. However, since the work of Dean and others, changes have occurred based on experience and end results. There is still uncertainty as to the relative value of preoperative radiation. Dean³⁹ has presented statistics that appear to demonstrate that in his group of all types of testicular tumors, the survival rate for the patients who had received preoperative irradiation was higher than that for patients who had received irradiation only after orchidectomy. Subsequent to the course of preoperative therapy, orchidectomy is performed about five to six weeks later. Preoperative irradiation has been opposed by some authors, including Smith, Dresser and Mintz,⁴⁰ Hinman and Powell⁴¹ and MacKenzie and Ratner.⁴²

Postoperative radiation after the primary orchidectomy has been widely used. Since the advent of the technic of protracted fractional doses of roentgen rays, this method or some modification of it has been most often employed. An increasing number of clinics use higher voltage in the treatment of testicular tumors as well as in other cancers. Others are of the opinion that the radiation is best carried out at potentials of the so-called moderate voltages (Nash and Leddy³⁶).

It is the consensus that roentgen therapy is of primary importance in the management of seminoma of the testis and has profoundly altered its prognosis. The results apparently are far different in the teratocarcinomas or mixed tumors which have shown a more variable resistance to the therapy. Recently more massive doses over longer periods have been suggested and used for these teratoids. Complicating damage to the stomach, intestines, liver and kidneys have occurred, but with the known fatal termination of these tumors when they have metastases, the risk of visceral damage is justified.

PROGNOSIS

For all practical purposes all neoplasms of the testicle are cancerous, with the prognosis for teratoid carcinomas poorer than that for seminomas. Simple castration by itself is not the therapeutic step of choice; in about 5 per cent of cases there is freedom from recurrence for more than five years. The radical operation in selected cases with experienced workers has given the highest percentage of relief. However, a large number of patients when seen have metastases and in these surgical treatment and radiation have resulted in a freedom from recurrence in a hopeful number of cases. Such cases may show tumor awakening and extension as late as ten years after therapy.

Clinical Notes, Suggestions and New Instruments

AUREOMYCIN IN OCULAR INFECTIONS

A Preliminary Report

ALSON E. BRALEY, M.D.
and
MURRAY SANDERS, M.D.
New York

In recent months, a mold belonging to the *Streptomyces* group has been isolated by workers¹ at the Lederle Laboratories, American Cyanamid Company. The antibiotic derived from this mold has been named "aureomycin," and numerous tests against gram-positive as well as against gram-negative organisms have strongly suggested that it might have an unusual degree of potency and range of activity. On the basis of information regarding the fundamental investigations² which the Lederle Laboratories provided us, it seemed desirable to test aureomycin in patients suffering with external diseases of the eye.

This new antibiotic has been used in 100 cases of ocular disease. For the most part, aureomycin was administered locally as a 0.5 per cent solution of a borate salt having a *pH* of 7.5 to 7.8 when dissolved in isotonic sodium chloride solution. The 0.5 per cent solution of the antibiotic was only mildly irritating to the noninflamed eye and was entirely nonirritating to the inflamed conjunctiva. The chemical properties of the drug will be described elsewhere, and this report is an attempt to evaluate its use as a local antibiotic. In a later study, the antibiotic activity of aureomycin will be compared with such other antibiotics as penicillin and streptomycin and with the locally administered sulfonamide drugs.

The borated solution is stable in the powder form but unstable in solution, although it retains most of its activity when kept at +4°C. In solution and at room temperature, the activity of the drug disappears in approximately twenty-four hours. Because of this rapid inactivation, it was felt that frequent use of the drug over a short period of time was the best method of application therefore, the majority of patients were treated for twenty-four to forty-eight hours. In a few instances a fresh supply of the antibiotic was furnished for use over a longer period. A few of the patients were given aureomycin hydrochloride intramuscularly in varying amounts, and the antibiotic in the doses used was entirely nontoxic to the patients.

The conjunctival sac of nearly all the patients was cultured for the presence of bacteria, and in some instances tissue culture and mice were inoculated in an effort to demonstrate the causative agent. In some of the patients it was not possible to determine the causative agent since several are unknown, such as vernal conjunctivitis and the Mooren's ulcer of the cornea.

STAPHYLOCOCCIC INFECTIONS

Of the patients treated, 56 had conjunctivitis produced by staphylococci either alone or combined with other organisms. Most of these patients had associated blepharitis and many had superficial punctate keratitis. The majority of patients with staphylococcal infection with associated blepharitis and keratitis were entirely healed within the first twelve to twenty-four hours. Many of the patients with staphylococcal conjunctivitis claimed to have had a remarkable effect within a matter of a few hours. Several of the patients were physicians who had had recurrent conjunctivitis for many years and who had become therapeutic nihilists. They were emphatically enthusiastic about the antibiotic and thought that the cure was even more rapid than with penicillin. No other form of treatment was

given to patients with staphylococcal conjunctivitis associated with blepharitis. No attempt was made to remove the crusts from the lid border except for culture purposes, and following the use of the drug for approximately twenty-four hours these crusts were stained yellowish. When the antibiotic therapy was discontinued, some of the patients had recurrences within thirty-six to seventy-two hours; however, if it could be replenished and used for two days, the number of recurrences decreased.

INFLUENZAL CONJUNCTIVITIS

Following the use of aureomycin in 4 cases of influenzal conjunctivitis, there were no recurrences. Recoveries occurred in less than twenty-four hours in all instances and were more rapid than with the usual form of therapy, since all the patients reported that there was no purulent discharge from the conjunctiva following the few applications of the antibiotic.

PNEUMOCOCCIC CONJUNCTIVITIS

Five patients with pneumococcal conjunctivitis were treated. After using aureomycin every hour for sixteen hours, they were entirely free of symptoms; there were no recurrences. As far as the clinical use of aureomycin is concerned, it was effective in pneumococcal conjunctivitis.

INCLUSION CONJUNCTIVITIS

Two patients with inclusion conjunctivitis have been treated with excellent results. The discharge, which had been profuse, was entirely gone within twelve hours, and the conjunctiva returned to normal within a week when "aureomycin" was used for forty-eight hours.

EPIDEMIC KERATOCONJUNCTIVITIS

Aureomycin was given to 13 patients in whom a positive diagnosis of epidemic keratoconjunctivitis could be made. Two patients were treated three days after the onset of symptoms,

Diseases Treated with Aureomycin and Number of Cases

Disease	No. of Cases
Staphylococcal conjunctivitis (necrosis and albus).....	56
Epidemic keratoconjunctivitis.....	13
Follicular conjunctivitis (unknown causation).....	9

Mooren's ulcer.....	2
Parinaud's conjunctivitis.....	1
Total.....	100

and both began to show immediate response. In 1 patient, S. G., the epidemic keratoconjunctivitis virus was isolated from a specimen obtained before treatment was started. She was treated with hourly drops and with 40 mg. intramuscularly, and the symptoms were entirely gone within a week. A few corneal opacities subsequently developed in each eye, but the clinical disease was shortened. Another patient, F. M., was given "aureomycin borate" locally, beginning on the third day of the disease. He was given a fresh supply every other day and used the antibiotic for two weeks. The acute phase of the disease was shortened, and after three weeks an occasional corneal opacity developed.

The majority of patients with epidemic keratoconjunctivitis were treated after the fifth day of the disease and received no beneficial effect. In none of these was the conjunctiva changed by continual application of the antibiotic. Three patients were treated after the disease had run its course, because of the presence of corneal opacities. Two of these patients were seen after the corneal opacities had developed and one when the conjunctivitis had begun to disappear, but blurring of vision due to edema of the cornea was severe. There is no effect from the antibiotic when treatment is started after the disease is established.

This paper was submitted for publication May 4, 1948.

From the Departments of Ophthalmology and Bacteriology, College of Physicians and Surgeons, Columbia University, New York.

DENDRITIC KERATITIS

Four patients with dendritic ulcers of the cornea have been treated. One patient gave a history of previous ulcers which had been dendritic in character, requiring cauterization. She was advised to return as soon as symptoms were noted. A foreign body sensation developed about six hours before her next examination. There was a typical dendritic figure in the lower part of the cornea with epithelial infiltration around the area of the ulcer. It was decided to use aureomycin locally for twenty-four hours, 1 drop at hourly intervals. The cornea was healed (except for one small area) in twenty-four hours, and forty-eight hours later the cornea was entirely clear. A child was admitted to the hospital for cautery of a dendritic ulcer and given aureomycin hourly overnight; by the time the patient was to go to the operating room for curettage of the ulcer, no ulcer could be observed. It is possible that both of these patients recovered spontaneously. The third patient was improved; the fourth showed little or no improvement following the prolonged use of aureomycin.

VERNAL CONJUNCTIVITIS

One patient with typical vernal conjunctivitis presented a large central corneal ulcer, the cause of which could not be determined. The ulcer healed promptly, and the patient observed that there was a decrease in the amount of itching and discharge as long as aureomycin therapy was continued. When treatment with the antibiotic was discontinued, there was a recurrence of itching and secretion. Because of this experience, 3 other patients with vernal conjunctivitis were treated with aureomycin borate. Two of these patients stated that they were relieved of symptoms as long as treatment with the antibiotic was continued, but the only objective difference was the lack of membrane on the conjunctiva. One patient with vernal conjunctivitis of some duration, who had received considerable roentgen therapy and in whom keratitis sicca subsequently developed, was unable to tolerate aureomycin locally.

ACUTE FOLLICULAR CONJUNCTIVITIS (CAUSE UNKNOWN)

There were 9 patients with acute follicular conjunctivitis treated with aureomycin. Studies of these patients failed to demonstrate a causative agent. All of the patients responded well to therapy, although some may have recovered spontaneously, and there were no recurrences. The period of morbidity was never beyond forty-eight hours.

PARINAUD'S CONJUNCTIVITIS

One patient with typical Parinaud's conjunctivitis was treated without beneficial effect. The normal progress of the disease was not shortened by the topical application of "aureomycin borate."

MOOREN'S ULCER

Two patients with marginal undermining advancing ulcers were treated. One had a typical Mooren's ulcer in one eye and was treated with penicillin, sulfonamide drugs, streptomycin and delimiting keratotomy, but the ulcer continued to extend, finally perforating, and the cornea became scarred. When the other eye became involved, the same treatment was instituted, but the ulcer was not controlled. Within forty-eight hours after local use of aureomycin there was no further extension of the ulcer, and the eye became clear; however, in spite of the continued use of aureomycin it was felt that the ulcer may have been extending and the treatment was discontinued.

The second patient had an atypical Mooren's ulcer that was a complete annular ulcer extending through the anterior two thirds of the cornea with an overhanging edge. The central area of the cornea was edematous and gray, and the ulcer in the second eye covered approximately two fifths of the lower part of the cornea. He was given penicillin locally and generally, and the cornea seemed to melt and the ulcer to extend. Scrapings were obtained from the margin of the ulcer and inoculated into tissue culture and subsequently into mice. He was then given intramuscular and local aureomycin therapy every hour. There was no further progression of the ulcer, and the one eye became white within a week. The eye in which there was decided edema of the central plug of the cornea became

moderately opaque, although the ulcer was controlled. The upper half of the cornea cleared, with the central area clearing as the upper half of the ulcer healed. The only opaque area remaining in the cornea was the lower half; this healed by pressure dressing. The vision improved from light perception to 20/50 in this eye and in the other eye from hand movements to 20/30. The tissue culture was contaminated with a gram-negative rod and staphylococci, and it was impossible to determine the exact cause of the ulcer.

COMMENT

Aureomycin appears to be an effective antibiotic agent against most of the gram-positive staphylococci. It seems to be at least as effective as penicillin when used locally. One disadvantage of its use in staphylococcal infections, particularly those associated with blepharitis, is that the solution is not present on the lid borders in very high concentration; if the crusts on the lid are stained yellow it is more effective. The use of the antibiotic in ointment form is being investigated. Another disadvantage of the compound when used in staphylococcal infections is recurrence, since the antibiotic is used for a short time. Recurrences, however, were no more frequent than with other antibiotics. Aureomycin is effective in all staphylococcal infections, provided that it can be used over a period of several days.

In influenzal conjunctivitis aureomycin produced excellent results, and it is much more effective than penicillin or the sulfonamide drugs. Within twenty-four hours the conjunctiva had returned to normal, and within a matter of hours the secretion was entirely absent.

Its effect when used locally in inclusion conjunctivitis is good; it seems to be more effective than the local use of sulfonamide drugs and as effective as the combination of oral and local treatment with sulfonamide drugs.

No patients with trachoma were treated in this series, but from previous experience it is anticipated that the antibiotic should be effective in this disease.

Use of the material in epidemic keratoconjunctivitis looks somewhat promising, although considerably more investigation will be necessary in order to determine its therapeutic effect. From the few patients treated, it would appear that the antibiotic may be effective during the first few days of the disease, but it will not prevent the development of a moderate number of corneal opacities. After the disease is established there is doubt that the antibiotic is effective. This is probably due to the fact that the virus is fixed in the tissue and aureomycin is not available to the cell in high enough concentration.

Its effectiveness in dendritic keratitis is inconclusive, although in this series 3 patients with clinical dendritic ulcers responded satisfactorily.

It is probable that the effect of aureomycin on vernal conjunctivitis is due entirely to the control of the secondary infection and not directly to the control of the cause of the conjunctivitis.

The solution was well tolerated by all of the patients; only occasionally did it produce irritation. Intramuscular injection of aureomycin hydrochloride is only slightly irritating and in the amounts used produces no changes in the blood picture or in the urine. No allergies and no toxic effects have been encountered.

CONCLUSIONS

1. Aureomycin borate in 0.5 to 1 per cent solution is non-irritating to the inflamed conjunctiva and only slightly irritating to the noninflamed conjunctiva.

2. Aureomycin borate is effective in 0.5 per cent concentration against staphylococci, pneumococci, influenza and inclusion conjunctivitis.

3. The antibiotic appears to be effective in cases of Mooren's ulcer and atypical Mooren's ulcer of unknown cause.

4. Aureomycin has some effect in epidemic keratoconjunctivitis, provided that treatment is started before the fourth day of the disease.

5. Aureomycin may be of value in dendritic keratitis.

6. Aureomycin is a valuable addition to our armamentarium of antibiotics.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports.

HOWARD A. CARTER, *Secretary*.

MEARS AUROPHONE HEARING AID MODEL 200 ACCEPTABLE

Manufacturer: Mears Radio Hearing Device Corp., 1 West Thirty-Fourth Street, New York 1.

Two forms of this hearing aid were submitted by the firm and subjected to adequate tests: (a) a model with crystal receiver, distinguished by a red grill cloth and (b) one with magnetic receiver, marked by a yellow grill cloth. The former model weighed 160 Gm. (5½ ounces); the latter 170 Gm. (5% ounces). The dimensions in each case were 110 by 18

by 68 mm. (4½ by ¾ by 2½ inches). Both are plastic-cased self-contained hearing aids, and in each a hinged bottom allows the entire front side to swing down to expose the batteries and instrument proper. The microphone is structurally isolated from the chassis by rubber band suspension. The receiver is connected to the instrument by a plastic-covered nonreversible cord with plugs at the ends.

For the A battery, each device requires two 1.5 volt dry cells

AuropHONE Model 200

of the zinc-carbon type in series; for the B battery, a 22.5 volt source.

1. *Crystal Receiver*.—The power consumption of this instrument was measured in an independent laboratory and was found to be 21 milliamperes at 2.9 volts for the A battery. For the B battery at 22 volts, the consumption was 0.29 milliamperes when quiet and 0.16 milliamperes in the presence of sound. Acoustical gain was also measured. The data here tabulated represent the decibel difference between the sound pressure at the face of the microphone of the instrument and the pressure produced by the receiver in a 2 cc. coupler. The pressure at the face of the microphone was held at approximately 60 decibels above zero for these measurements (60 decibels above 0.0002 dyne per square centimeter) and the volume control was set at "full." Readings were made at seven different frequencies and three settings of the tone control:

Tone		Frequencies						
		200	500	1,000	1,200	2,200	3,000	4,000
1	Noise	42	57	50	38	39	30	
2	Noise	28	49	43	33	33	25	
3	Noise	28	40	29	25	23	14	

The following are approximate values of maximum sound pressure levels (at three frequencies) in a 2 cc. coupler with the volume control set for full gain and the tone control set at position 1:

Frequency	Input Level	Maximum Output Level
600	90	126
1,000	90	140
2,600	90	132

Intelligibility tests were made with a person of normal hearing seated inside a booth giving about a 30 decibel sound reduction. The speaking person was outside the booth using

normal speaking voice. Score made with the Harvard no. 9 lists under these critical conditions was 95 per cent.

2. *Magnetic Receiver*.—The power consumption of this instrument was similarly measured and found to be 29 milliamperes at 2.9 volts for the A battery. For the B battery at 22 volts, the consumption was 0.49 milliamperes when quiet and 0.42 milliamperes in the presence of sound. Measurements of acoustical gain were made under the conditions described, with the following results:

Tone	200	500	1,000	1,200	2,200	3,000	4,000
1	39	50	52	55	41	53	40
2	Noise	30	42	46	36	49	36
3	Noise	30	42	46	36	49	32

The following are approximate values of maximum sound pressure levels, at three frequencies, in a 2 cc. coupler with the volume control set for full gain and the tone control set at position 1:

Frequency	Input Level	Maximum Output Level
600	90	132
1,000	90	132
1,300	85	132

Intelligibility tests were made with a person of normal hearing seated inside a booth giving about a 30 decibel sound reduction. The speaking person was outside the booth using normal speaking voice. Score made with the Harvard no. 9 lists under these critical conditions was 80 per cent.

The Council on Physical Medicine voted to include the Mears AuropHONE Hearing Aid, Model 200, with crystal and magnetic receivers, in its list of accepted devices.

MAICO D-9 AUDIOMETER ACCEPTABLE

Manufacturer: The Maico Company, Inc., North Third Street, Minneapolis 1.

The Maico Audiometer, Model D-9, is a discrete frequency instrument designed to present pure tone stimuli at 64, 128, 256, 512, 1,024, 2,048, 2,896, 4,096, 5,792, 8,192 and 11,584 cycles per second for the clinical testing of hearing. In general arrangement it resembles the previously accepted Model D-5, which it is intended to supersede. The instrument is encased in a wood cabinet and has an inclined panel. Controls are clearly marked and arranged as in the D-5.

The audiometer weighs 11.3 Kg. (25 pounds) and measures 45.4 by 25 by 19.4 cm. (17½ by 9¾ by 7¾ inches). The carrying case weighs 6.8 Kg. (15 pounds) and measures 63 by 29 by 22 cm. (25 by 11½ by 8¾ inches).

The D-9 model is supplied with both air and bone conduction receivers, a signal switch for responses by the patient, a masking circuit that feeds a magnetic head phone, a speech circuit for communicating with severely hard of hearing patients and a headband for the various receivers.

The instrument was tested in two types of situation, one a clinic where routine audiometric tests were given to hard of hearing patients, and the other a field program for testing adults. In addition, measurements were made of air conduction thresholds yielded by normal ears, bone conduction thresholds for the same, aerial radiation from the bone receiver, efficiency of masking tone, properties of the attenuation system, wave form of signal and residual noise. Results of these tests indicated that the instrument was satisfactory in both types of situation.

The Council on Physical Medicine voted to include the Maico Audiometer, Model D-9, in its list of accepted devices.

Maico D-9 Audiometer

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

PROMETHESTROL DIPROPIONATE.—Meprane Dipropionate—Reed & Carnrick.—Dimethylhexestrol dipropionate. — 3,4-Bis-(*m*-methyl-*p*-propionyphenyl) hexane. — $C_{28}H_{38}O_4$.—M. W. 410.53.—The structural formula of promethestrol dipropionate may be represented as follows:

Actions and Uses.—Promethestrol Dipropionate is similar in its actions to diethylstilbestrol and other synthetic estrogens. It is used for the same conditions for which estrogenic substances are employed and the contraindications are those of the natural estrogens.

Dosage.—In the menopause, treatment may be started with 1 mg. given three times daily, gradually reducing the dosage to 1 mg. daily. For suppression of lactation, 3 to 5 mg. daily.

Tests and Standards.—

Promethestrol dipropionate occurs as a white, odorless crystalline powder, melting between 113 and 116 C. It is freely soluble in benzene, ether and ethyl acetate; slightly soluble in alcohol; and practically insoluble in water, dilute acids and dilute alkalis. A solution of promethestrol dipropionate in 90 per cent alcohol is neutral to litmus.

Dissolve about 10 mg. of promethestrol dipropionate in 1 cc. of sulfuric acid: an orange-red solution is obtained. Dilute (caution!) with 10 cc. of water: a pink, turbid solution is formed, which becomes white after standing for several minutes (distinction from benzestrol, diethylstilbestrol, ethyl estradiol, hexestrol and mestibol.)

Add 1 drop of ferric chloride T.S. to 2 cc. of a saturated solution of promethestrol dipropionate in diluted alcohol. The color is no different than that obtained by adding ferric chloride T.S. to the solvent (distinction from benzestrol, diethylstilbestrol, hexestrol and mestibol, which give a slight greenish-yellow color when the reagent is added).

Dry about 1 Gm. of promethestrol dipropionate, accurately weighed, in a vacuum desiccator over phosphorus pentoxide at room temperature for 24 hours; the loss in weight does not exceed 0.5 per cent.

Char about 0.5 Gm. of promethestrol dipropionate accurately weighed, over a low flame. Cool, then add 1 cc. of sulfuric acid and continue ignition until no carbon remains; no more than 0.05 per cent of residue results.

Place about 0.25 Gm. of promethestrol dipropionate, accurately weighed, in a 125 cc. Erlenmeyer flask containing 10 cc. of 0.5 N alcoholic sodium hydroxide. Reflux gently for 2 hours, cool and titrate the excess base with 0.1 N sulfuric acid, using phenolphthalein T.S. as indicator. The saponification equivalent (obtained by dividing the mass of promethestrol dipropionate used in milligrams by the number of cc. of 1 N sodium hydroxide consumed in the saponification) is not less than 203 nor more than 210.

Add about 75 cc. of water and 2 cc. of sulfuric acid to the samples used in determining the saponification number. Distill and collect about 50 cc. of the distillate. Titrate a 10 cc. portion (A) of the distillate with 0.01 N sodium hydroxide. Redistill the remaining 40 cc. of distillate, collecting three 10 cc. fractions (B, C, D). Titrate each fraction with 0.01 N sodium hydroxide. The Duclaux numbers 10B/A, 10C/A and 10D/A should be between 10 and 12.

Accurately weigh about 0.25 Gm. of promethestrol dipropionate, previously dried to constant weight over phosphorus pentoxide, and reflux this sample for 1 hour in 10 cc. of 15 per cent methanolic potassium hydroxide. Cool, add 100 cc. of water and quantitatively transfer the solution to a separatory funnel. Acidify with 10 per cent hydrochloric acid and extract with four 50 cc. portions of ether. Wash the combined ether extracts with three 100 cc. portions of 5 per cent sodium bicarbonate and with two 100 cc. portions of water. Filter the ether solution into a tared beaker, wash the funnel and filter paper once with ether and then evaporate slowly on a water bath to constant weight. The weight of 3,3'-dimethylhexestrol obtained in the previous assay is dissolved in 5 cc. of 5 per cent sodium hydroxide and 1 cc. of benzoyl chloride is added slowly with constant shaking. Continue shaking for 10 minutes after the addition of the benzoyl chloride and then add diluted ammonia solution until a distinct ammoniacal odor is present. Shake for an additional 10 minutes, remove the solid by filtration, wash several times with water and then with ethanol, and dry. The 3,3'-dimethylhexestrol dibenzoate obtained melts between 200 and 208 C.

PROMETHESTROL DIPROPIONATE TABLETS.—Accurately weigh a sufficient number of promethestrol dipropionate tablets to contain 50 mg. of the drug and grind them to a powder. Transfer an accurately weighed quantity of this powder, equivalent to about 20 mg. of the drug, to a 50 cc. glass-stoppered graduated cylinder. Extract the solid by shaking with four 20 cc. portions of ether. Allow the suspended material to

settle after each extraction. Decant the ether and filter into a tared beaker. Wash the filter paper with a 20 cc. portion of ether, collecting it in the same beaker as the extracts. Evaporate the combined filtrates and dry the residue to constant weight in a vacuum desiccator over phosphorus pentoxide. The quantity of 3,4-bis-(*m*-methyl-*p*-propionyphenyl)hexane is not less than 90 nor more than 110 per cent of the labeled amount.

The extracted material responds to the identification tests listed in the monograph on promethestrol dipropionate.

Small amounts of promethestrol dipropionate may be determined colorimetrically. A quantity of powdered tablet material sufficient to contain 1 mg. of the drug is weighed accurately and transferred to a 125 cc. Erlenmeyer flask containing 10 cc. of alcohol and three drops of sulfuric acid. Reflux the suspended material for 2 hours and quantitatively transfer the contents to a 100 cc. volumetric flask. Wash the Erlenmeyer flask with three 10 cc. portions of diluted alcohol and add the washings to the volumetric flask. Add 2 cc. of diluted hydrochloric acid and 4 cc. of molybdo-phosphotungstate T.S. and 20 cc. of water. Shake the mixture thoroughly and allow to stand for 10 minutes. Add 10 cc. of 25 per cent sodium carbonate (anhydrous) and dilute to 100 cc. with water. Shake and then allow the reaction mixture to stand for about 1 hour. Filter the solution and compare at 580 mμ with a standard and blank run simultaneously with the unknown.

REED & CARNICK, JERSEY CITY, N. J.

Tablets Meprane Dipropionate: 1 mg.

U. S. patent applied for.

PROPYLTHIOURACIL.—6-propyl-2-thiouracil.— $C_7H_{10}N_2OS$.—M. W. 170.226. The structural formula of propylthiouracil may be represented as follows:

Actions and Uses.—Propylthiouracil interferes with the formation of thyroxin by the thyroid gland. It is useful in the treatment of hyperthyroidism, thyrotoxicosis and thyroiditis. It is of no value and should not be used in other derangements of thyroid activity or in conditions not associated with hyperthyroidism.

Since propylthiouracil does not inactivate or interfere with the action of thyroxin already formed and stored in the gland, the effects of propylthiouracil medication do not appear until this store of thyroxin has been utilized. It may take several days to several weeks for the signs of decreased thyroid activity to become manifest, particularly if the patient has received previous iodine therapy.

Not all patients experience a permanent remission following propylthiouracil therapy, and the duration of treatment necessary to secure permanent relief from hyperthyroidism has not been determined. On the basis of the available information, it can be recommended only that propylthiouracil be used for pre-operative treatment or for those patients for whom operation is contraindicated. The wisdom of depending on propylthiouracil as a substitute for operative procedure can be determined only by following the results of investigations carried on for longer periods.

Propylthiouracil is capable of producing adverse reactions in some patients. The incidence and severity of these reactions are unpredictable, but they occur with less frequency than do those following medication with the parent compound, thiouracil. The severest complication of propylthiouracil therapy is granulocytopenia. Less severe reactions may include leukopenia, drug fever and dermatitis. The drug should be discontinued and appropriate therapy commenced immediately on the detection of signs of any of these complications.

Since the mild and the juvenile types of hyperthyroidism can frequently be controlled adequately by iodine therapy alone, propylthiouracil should not be used for these patients unless the safer form of therapy proves ineffective.

Dosage.—For severe cases of hyperthyroidism, initial doses of 50 mg. of propylthiouracil every eight hours appear to be effective in routine treatment, and 50 mg. twice daily in milder cases. Iodine should be administered for two or three weeks immediately before thyroidectomy.

The effective dosage of propylthiouracil should be continued until all signs and symptoms of the disease have been brought under control. Adequate maintenance dosage may best be established by determinations of the basal metabolic rate. Patients should be instructed to cease medication and report to their physician immediately if any adverse symptoms such as sore throat, fever, coryza or malaise are experienced.

Tests and Standards.—

Propylthiouracil occurs as a bitter, white, powdery, crystalline substance of starchlike appearance to the eye and to the touch. It melts sharply in the range of 218 to 220 C. It is sparingly soluble in alcohol,

slightly soluble in chloroform and ether, very slightly soluble in water and practically insoluble in benzene.

Add 1 cc. of strong ammonia solution to 25 mg. of propylthiouracil: complete solution occurs (25 mg. of thiouracil will not completely dissolve in 1 cc. of strong ammonia solution).

Slowly add bromine water to about 25 mg. of propylthiouracil in a test tube until complete solution is effected. Discharge the color with heat. Cool and add 10 cc. of barium hydroxide T. S.: a white precipitate forms (distinction from thiouracil, which yields a white precipitate that turns purple within a minute).

Dry 0.5 Gm. of propylthiouracil, accurately weighed, to constant weight at 100 C.: the loss in weight does not exceed 0.5 per cent.

Char about 0.5 Gm. of propylthiouracil, accurately weighed; cool, add a few drops of sulfuric acid to the cooled mass and ignite: the amount of residue is not more than 0.1 per cent.

Add 4 cc. of water and 1 cc. of silver nitrate T. S. to 0.5 Gm. of propylthiouracil in a test tube. Add 5 cc. of nitric acid and allow the solution to stand until the reaction is complete. Expel the oxides of nitrogen by heating; dilute with 10 cc. of water, and cool to room temperature: the turbidity does not exceed that of 0.1 cc. of fiftieth-normal hydrochloric acid used as a control (chlorides).

Heat 25 cc. of water containing 0.5 Gm. of propylthiouracil for ten minutes on a steam bath. Cool, filter and wash the filter paper; adjust the volume of the filtrate to 25 cc. with the washings. Add 1 cc. of barium chloride T. S. and 1 cc. of diluted hydrochloric acid: the turbidity does not exceed that of 0.1 cc. of fiftieth-normal sulfuric acid used as a control (sulfates).

Dissolve 1 Gm. of the propylthiouracil in sufficient sodium hydroxide T. S. to give complete solution, and dilute to 20 cc. with water. Add 5 drops of sodium sulfide T. S.: no more turbidity develops than corresponds to 20 parts per million of lead (U. S. P. XIII).

Weigh, accurately, about 0.5 Gm. of propylthiouracil and transfer to a 400 cc. beaker containing 100 cc. of neutralized alcohol. Add 5 drops of phenolphthalein T. S. Slowly titrate with tenth-normal sodium hydroxide, stirring constantly until complete solution is effected. Continue the titration to the first visible pink color. Each cubic centimeter of tenth-normal sodium hydroxide solution is equivalent to 0.01702 Gm. of propylthiouracil: the propylthiouracil content is not less than 95 nor more than 105 per cent.

PROPYLTHIOURACIL TABLETS: Weigh, accurately, 20 propylthiouracil tablets and grind them to a fine powder. Transfer about 400 mg., accurately weighed, to a 400 cc. beaker containing 100 cc. of neutralized ethyl alcohol. Add 5 drops of phenolphthalein T. S. Slowly titrate with tenth-normal sodium hydroxide, stirring constantly. Continue the titration to the first visible pink color. Each cubic centimeter of tenth-normal sodium hydroxide solution is equivalent to 0.01702 Gm. of propylthiouracil: the propylthiouracil content is not less than 93 nor more than 105 per cent of the claimed amount.

METHIONINE.—"Meonine"—Wyeth.—DL-Methionine.— γ -Methylthio- α -aminobutyric acid.— $C_4H_9NO_2S$.—M. W. 149.21.
—The structural formula for DL-Methionine may be represented as follows:

Actions and Uses.—Methionine is a sulfur containing amino acid which is considered to be an indispensable dietary component. It is available in synthetically prepared racemic form that may be administered in sufficient quantity to provide amounts equivalent to the biologically active levo form.

In animal experiments, certain deficient diets, especially those low in protein and high in fat, will cause liver damage in almost all animals, and, in addition, renal damage in some. That these pathological changes can be prevented by the addition to the diet of methionine alone is of great theoretical interest; similar protection can be obtained by casein, and doubtless by other common foodstuffs, as less rigorously restricted diets do not produce hepatic lesions.

Severe liver damage is regularly caused in protein depleted dogs by chloroform anesthesia and this is altogether prevented by methionine. Lean beef and other high protein diets are equally effective. A similar protective effect has been demonstrated against other hepatotoxic agents such as oxophenarsine in animal experiments.

The striking results of these animal experiments have led to the use of methionine in the treatment of liver disease in man, especially in hepatic cirrhosis, acute hepatitis and toxic hepatitis due to carbon tetrachloride and T.N.T. poisoning. In all these studies, methionine was used as a supplement to other standard methods of treatment such as high protein diet and vitamins. The improvement which sometimes follows cannot be attributed to the methionine alone.

There is at present no valid evidence that pure methionine is superior as a therapeutic agent to a high protein diet containing foodstuffs, such as casein and eggwhite, which contain methionine in large amounts. But because of its great theoretical

interest and in the hope that some special utility may be found, methionine has been accepted for experimental purposes only.

Of low toxicity, the use of methionine is not likely to be attended by any untoward effects.

Dosage.—As a supplement to a high protein diet, 3 to 6 Gm. daily is usually administered in tablet form. In severe cases 10 to 20 Gm. has been used. When oral administration is not feasible, crystalline methionine may be given in amounts of 5 to 10 Gm. daily by slow intravenous drip as a 3 per cent solution in Dextrose Injection, U. S. P., or Water for Injection, U. S. P., that has been further sterilized by autoclaving.

Tests and Standards.—

DL-Methionine occurs as white, crystalline platelets or a powder, having a faint odor. It is soluble in water, dilute acids and dilute alkalis; very slightly soluble in alcohol; and practically insoluble in ether. A 1 per cent aqueous solution of DL-methionine exhibits a pH in the range 5.6-6.1, and is optically inactive.

Dissolve 4.5 Gm. of DL-methionine in 150 cc. of water. The solution is clear and colorless. To 25 cc. of this solution add 1 cc. of diluted hydrochloric acid and 2 cc. of barium chloride T. S. The turbidity is less than that shown by 0.4 cc. of 0.02 N sulfuric acid diluted to 25 cc., and treated in a similar manner (sulfate). To another 25 cc. portion add 1 cc. of nitric acid and 1 cc. of silver nitrate T. S. The turbidity is not more than that obtained when 0.2 cc. of 0.02 N hydrochloric acid is diluted to 25 cc., and treated in the same manner (chloride). Add 1 cc. of 1 N sodium hydroxide and 1 drop of Nessler's reagent T. S. to 25 cc. of the DL-methionine solution: the color developed is less than that produced by 25 cc. of a solution containing 0.0125 mg. of ammonium chloride (ammonium salts). Add 1 cc. of 4 N hydrochloric acid to 25 cc. of the solution and then add 10 cc. of hydrogen sulfide T. S. The color produced is less than that obtained when 1.5 cc. of standard lead solution (U. S. P. XIII) is diluted to 25 cc., acidified and treated with hydrogen sulfide T. S. (heavy metals). To the solution containing DL-methionine, used in the test for heavy metals, add 2 cc. of ammonia T. S.: the green color obtained is no darker than that produced by treating the blank from the heavy metals test with 1 cc. of ferric chloride solution containing about 0.05 mg. iron (made by diluting 1 cc. of ferric chloride colorimetric solution, U. S. P. XIII, to 200 cc.), mixing, and adding 2 cc. of ammonia T. S.

Add about 25 mg. of dry DL-methionine to about 1 cc. of saturated solution of anhydrous copper sulfate in sulfuric acid: the appearance of a yellow color indicates methionine.

Dissolve about 5 mg. of DL-methionine in 5 cc. of water and then add in succession, shaking after each addition, 1 cc. of 5 N sodium hydroxide, 1 cc. of 1 per cent glycine, and 0.3 cc. of 10 per cent sodium nitroprusside (freshly prepared). Keep at 35-40 C. for 10 minutes, and then cool in an ice-bath for 2 minutes. Add 2 cc. of 20 per cent hydrochloric acid and shake the mixture: the appearance of a reddish-purple color indicates methionine.

Dry about 1.5 Gm. of DL-methionine, accurately weighed, at 100 C. for 4 hours: the loss in weight does not exceed 0.5 per cent.

Char about 1 Gm. of DL-methionine, accurately weighed, over a low flame. Cool, add 1 cc. of sulfuric acid and continue ignition until no carbon remains: the residue does not exceed 0.05 per cent.

Transfer about 0.1 Gm. of dry DL-methionine, accurately weighed, to a semi-micro Kjeldahl flask and digest with 5 cc. of sulfuric acid, 2 Gm. of potassium sulfate, 0.2 Gm. of copper sulfate and 1 cc. of 30 per cent hydrogen peroxide. Dilute the clear solution to 10 cc., make alkaline with 40 per cent sodium hydroxide, and distill the ammonia into 50 cc. of 0.02 N sulfuric acid. Titrate the excess acid with 0.02 N sodium hydroxide, using methyl red T. S. as an indicator: the nitrogen content is not less than 9.2 nor more than 9.5 per cent.

Weigh, accurately, about 0.3 Gm. of DL-methionine, transfer quantitatively to a 100 cc. volumetric flask and fill to the mark with distilled water. Transfer a 5 cc. portion of the solution to an Erlenmeyer flask and add 2 cc. of phosphate buffer (7 volumes of 1 M KH_2PO_4 and 3 volumes of 1 M K_2HPO_4) and 2 cc. of iodine solution, approximately 0.1 N. Permit the mixture to stand for about 15 minutes and then remove the excess iodine with 0.1 M sodium thiosulfate solution, using starch-potassium iodide T. S. as an indicator. Add 2.5 cc. of 2 N hydrochloric acid and titrate the iodine liberated with 0.025 N sodium thiosulfate. Perform a blank determination on 5 cc. of the DL-methionine solution as follows: add 1 cc. of 6 N hydrochloric acid and enough 0.1 M potassium iodate solution to give a persistent yellow color. Allow the solution to stand for about 15 minutes and then add 1 cc. of 5 N potassium iodide solution. Add about one-half the sodium hydroxide needed for neutralization (3 cc. of 1 N) followed by a mixture of the remainder of the sodium hydroxide and 3 cc. of the phosphate buffer. Add 2 cc. of 5 N potassium iodide solution and allow to stand for 10 minutes. Remove the excess iodine with 0.1 M sodium thiosulfate solution, add 2 cc. of 2 N hydrochloric acid and titrate the iodine liberated. Subtract the amount of thiosulfate used in the blank from that used in the determination: 1 cc. of 0.025 N sodium thiosulfate is equivalent to 0.001865 Gm. of methionine. The percentage of methionine should be not less than 98.5 nor more than 101 per cent.

TABLETS: The pulverized tablets respond to the identification tests and assay described in the monograph on DL-Methionine. Each tablet should contain not less than 95 nor more than 105 per cent of the claimed amount of DL-methionine.

WYETH INCORPORATED, PHILADELPHIA

Crystalline Meonine (Powder): 50 Gm. bottles.

Tablets Meonine: 0.5 Gm.

U. S. trademark 406,590.

SODIUM ASCORBATE INJECTION U. S. P. (See New and Nonofficial Remedies 1947, p. 520).

The following dosage form has been accepted:

THE CENTRAL PHARMACAL CO., SEYMOUR, IND.

Solution Sodium Ascorbate: 100 mg. per cc., 10 cc. vials.

METHYLTESTOSTERONE.—U. S. P.—17-Methyltestosterone.—17-methyl- Δ^1 -androstene-17-(a)-ol-3-one, $C_{28}H_{48}O_2$.—M. W. 302.44. The structural formula of methyltestosterone may be represented as follows:

For description and standards see the U. S. Pharmacopeia under Methyltestosterone and Methyltestosterone Tablets.

Actions and Uses.—Methyltestosterone may be given orally in the treatment of gonadal failure in the male. Its actions and uses are qualitatively the same as those for testosterone propionate.

Dosage.—The dosage and duration of methyltestosterone therapy vary considerably, depending on the condition, its severity, previous androgenic administration and individual variation. It is usually preferable to begin therapy with a low dose, about 5 mg. daily, increasing to 10 mg. or 15 mg. if higher doses appear indicated.

RAHE CHEMICALS, INC., HARRISON, N. J.

Tablets Methyltestosterone: 10 mg. and 20 mg.

ALUMINUM HYDROXIDE GEL (See New and Non-official Remedies 1947, p. 315).

The following dosage has been accepted:

WM. R. RORER, INC., PHILADELPHIA

Tablets Dried Aluminum Hydroxide Gel (Flavored): 0.3 Gm.

CHORIONIC GONADOTROPIN (See New and Non-official Remedies 1947, p. 374).

The following dosage form has been accepted:

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Entromone (Powder): 5,000 I. U. and 10,000 I. U., 10 cc. vials. Powdered preparations of chorionic gonadotropin, which when diluted with 9 cc. of the accompanying isotonic solution of sodium chloride and preserved with phenol 0.4 per cent, provides solutions having a potency of 500 or 1,000 international units per cc. respectively.

U. S. patent 1,910,298; U. S. trademark 354,550.

DIENESTROL (See THE JOURNAL, Nov. 22, 1947, p. 773).

The following additional dosage form has been accepted:

WHITE LABORATORIES, INC., NEWARK, N. J.

Aqueous Suspension Dienestrol: 5 mg. per cc., 10 cc. vials. Preserved with chlorobutanol 0.5 per cent.

U. S. patent applied for.

ESTROGENIC SUBSTANCES (WATER INSOLUBLE) (See New and Nonofficial Remedies 1947, p. 343).

The following dosage forms have been accepted:

BIORGANIC LABORATORIES, INC., BROOKLYN

Estrogenic Substances: Bulk.

ENDO PRODUCTS, INC., RICHMOND HILL, N. Y.

Aqueous Suspension Estromone: 20,000 I. U. per cc., 10 cc. vials.

THE NATIONAL DRUG CO., PHILADELPHIA

Solution Estronate in Oil: 5,000 I. U. per cc. in corn oil, 10 cc. Injectosols; 10,000 I. U. per cc. in corn oil, 1 cc. ampuls, 10 cc. and 25 cc. Injectosols; and 20,000 I. U. per cc. in corn oil, 10 cc. and 25 cc. Injectosols. Preserved with chlorobutanol 0.5%.

PROCAINE HYDROCHLORIDE (See New and Non-official Remedies, 1947, p. 57).

The following dosage form has been accepted:

LINCOLN LABORATORIES, INC., DECATUR, ILL.

Solution Procaine Hydrochloride 2%: 100 cc. vial. Each cubic centimeter contains procaine hydrochloride 2 per cent in distilled water. Preserved with chlorobutanol 0.5 per cent.

MEPERIDINE HYDROCHLORIDE (See New and Nonofficial Remedies 1947, p. 28).

The following additional dosage form has been accepted:

WINTHIROP-STEARNES, INC., NEW YORK

Tablets Demerol Hydrochloride: 100 mg.

PERTUSSIS VACCINE (See New and Nonofficial Remedies 1947, p. 457).

The following dosage form has been accepted:

CUTTER LABORATORIES, BERKELEY, CALIF.

Pertussis Vaccine: 20,000 million *H. pertussis* per cc., 5 cc., 20 cc. and 50 cc. vials; and 40,000 million *H. pertussis* per cc., 2.5 cc., 10 cc. and 25 cc. vials. Preserved with sodium ethyl mercuri thiosalicylate 1:10,000 and phenol 0.25 per cent.

PENICILLIN (See New and Nonofficial Remedies 1947, p. 144).

The following dosage forms have been accepted:

E. R. SQUIBB & SONS, NEW YORK

Crystalline Procaine Penicillin G in Oil: 300,000 units in peanut oil, 1 cc. and 10 cc. vials suspended with 2% aluminum monostearate; 1 cc. double-cell cartridges with Aspiring Test Solution preserved with chlorobutanol 0.5 per cent in packages of five cartridges; 1 cartridge with disposable syringe and needle and 1 cartridge with sterile hypodermic needle alone for use with metal B-D cartridge syringe assembly.

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Crystalline Penicillin G Potassium: 100,000, 200,000, 500,000 and 1,000,000 unit vials.

BIO-RAMO DRUG COMPANY, BALTIMORE

Penicillin Calcium in Oil and Wax: 300,000 units per cc., 10 cc. vials.

PREMO PHARMACEUTICAL LABORATORIES, NEW YORK

Crystalline Procaine Penicillin G in Oil: 300,000 units per cc., in sesame oil, 10 cc. vials.

HUMAN SERUM IMMUNE GLOBULIN.—The gamma globulin fraction of normal adult human plasma. The finished product contains 16.5% of gamma globulin and complies with the minimum requirements of the National Institute of Health and as prepared by an acceptable method.

Actions and Uses.—For modification or complete protection against measles.

Dosage.—The volume of the dose per pound of body weight is 0.02-0.025 cc. for modification and at least 0.1 cc. for prevention when the product contains 150 mg. of gamma globulin per cc.

CUTTER LABORATORIES, BERKELEY, CALIF.

Immune Serum Globulin (Human): 2 cc. vials. Preserved with sodium ethyl mercuri thiosalicylate 1:10,000.

Licensed by Research Corporation. U. S. patent No. 2,390,074.

POISON IVY-SUMACH EXTRACT.—A solution of the combined resin extracted from the fresh leaves of *Rhus toxicodendron* rodicon and *Rhus toxicodendron* vernix.

Actions and Uses.—Poison Ivy-Sumach Extract is used for prevention of the symptoms of the dermatitis produced through contact with *Rhus toxicodendron* rodicon and *Rhus toxicodendron* vernix.

Dosage.—Three injections of 0.1 cc., 0.2 cc. and 0.4 cc. on successive days.

BARRY LABORATORIES, INC., ALLERGY PRODUCTS DIVISION, DETROIT

Poison Ivy-Sumac Extract: Packages of four vials each containing 0.7 cc. of concentrated extract and three vials each containing 0.9 cc. diluent; also in 15 cc. vials of concentrated extract. The diluent contains 0.5% procaine hydrochloride, and is preserved with 0.4% chlorobutanol in physiologic solution of sodium chloride.

Preparation.—

The oily substance which is extracted with suitable solvents from the fresh leaves of *Rhus toxicodendron* rodicon and *Rhus toxicodendron* vernix is purified and decolorized. The resultant oily resin is dissolved in alcohol and standardized to represent a 1:500 dilution.

SATURDAY, OCTOBER 9, 1948

CHLOROMYCETIN

From a soil sample collected in a mulched field near Caracas, Venezuela, Burkholder¹ of Yale University isolated a new strain of *Streptomyces*. Agar streak cultures of this organism were found to inhibit adjacent inoculums of a wide variety of gram-positive and gram-negative micro-organisms, including: *Bacillus subtilis*, *S. aureus*, *Brucella abortus*, *Escherichia coli*, *Klebsiella pneumoniae*, *Salmonella schottmuelleri* and *Shigella paradysenteriae*. When the Burkholder *Streptomyces* was grown in shaken flasks of liquid mediums, filtrates proved to possess antibacterial activity in broth dilutions against the same micro-organisms. From these filtrates a crystalline product was isolated, which was named "chloromycetin."

This crystalline material inhibits the growth of a wide range of gram-positive and gram-negative bacteria when tested in dilutions as high as 0.35 microgram per cubic centimeter. This is a higher effective dilution than that of the earlier antibiotics. Of particular interest was his observation that chloromycetin when injected into chick embryos shows chemotherapeutic activity against several rickettsial and virus diseases. Similar therapeutic results were noted in infected mice. Moreover, in contrast with streptomycin, chloromycetin is rapidly absorbed from the gastrointestinal tract of laboratory animals, and is apparently nontoxic even when given intravenously in massive doses.

More detailed studies of the therapeutic effects of this new antibiotic were undertaken by Smadel and Jackson² of the Army Medical Center, Washington, D. C. Initial tests were performed with groups of twenty-four 7 day embryonated eggs, infected by the yolk sac route with *Rickettsia orientalis*, *Rickettsia prowazeki*, *Rickettsia mooseri* or *Dermacentroxenus rickettsi*. Eggs were examined daily and the time of death noted. All untreated control eggs died of the infection. It was found that as little as 0.125 mg. chloromycetin given at the time of infection would definitely prolong life. Doses as large as 1 mg. per

egg would reduce the mortality by at least 65 per cent. Sixteen of the 24 treated eggs survived to the fifteenth day after infection, and 8 hatched normally. Similar therapeutic effects were recorded with embryonated eggs infected with psittacosis virus, variola virus or influenza A virus.

Similar therapeutic effects were noted in mice infected with scrub typhus. Daily intraperitoneal injections of as little as 0.1 mg. per mouse, started one day after infection, reduced the mortality by 62.5 per cent, while 1.5 mg. doses similarly given reduced the mortality to zero. With a 2.5 mg. intraperitoneal dose, the treatment could be delayed for five to eight days and still be equally effective. If delayed till the tenth day this intraperitoneal dose would save but 60 per cent of the infected mice. By doubling the dosage chloromycetin was equally effective if given orally. Chloromycetin was equally effective with mice infected with Japanese encephalitis.

So far as noninfected control mice and embryonated eggs which received the maximum doses of chloromycetin remain unaffected, the new antibiotic is apparently without appreciable toxicity. On account of this apparently low toxicity, the ready absorption of chloromycetin from the alimentary tract and its beneficial effects when given relatively late in experimental disease, Smadel and his associates suggested that chloromycetin might be of value in human medicine.

As a preliminary to a proposed study of its therapeutic value, Smadel³ and his associates administered single or repeated oral doses to a group of physician volunteers. After a single dose of 2 Gm. appreciable amounts of the drug were demonstrable within thirty minutes in both blood and urine. The titers decreased to zero by the end of eight hours. From this rapid elimination of the drug frequent oral administration is indicated in order to maintain the antibiotic at an appreciable level in the blood stream. With a 1 Gm. initial dose followed by 0.2 Gm. doses every four hours, the antibiotic can be maintained at an effective level in the blood. Approximately 10 per cent of the total amount thus given was recovered in active form from the urine. Toxic effects were not observed by the volunteer physicians during or after such administration.

After this preliminary work on normal volunteers a group of 5 patients with typhus were treated with the same oral doses.⁴ The diagnosis was confirmed by positive Weil-Felix and specific rickettsial agglutination reactions. Treatment was begun between the fifth and the eighth day of the disease. At this time three of the patients exhibited a high grade fever, high pulse rate and a plus 2 to plus 3 rash. One patient was in delirium. Each patient was given an initial oral dose of 1 to 2 Gm. chloromycetin, followed by a 0.2 Gm. oral dose every four hours. In all cases there was a

rapid fall in pulse rate and body temperature. The delirium disappeared within three days. The rash disappeared within three to five days. Toxic reactions were not noted.

Comparison was made with an equal number of patients with typhus not treated with the new antibiotic. On the basis of these limited comparisons Smadel and his associates concluded that the administration of chloromycetin to patients with typhus is a safe procedure and that the therapeutic effects are sufficiently encouraging to warrant further tests of the drug with rickettsial and virus diseases.

More extensive tests of this drug were made by the Malaya Institute of Medical Research, during the recent outbreak of scrub typhus at Kuala Lumpur.⁵ Twenty-five hospitalized patients were treated with chloromycetin, while 12 untreated hospitalized patients served as controls. Treatment was begun on an average 6.2 days after the onset of the infection. All treated patients became afebrile within an average of thirty hours after the initial dose. The untreated patients remained febrile for an average of eighteen days. Rickettsemia disappeared within twenty-four hours after the initial dose, and the rash within forty-eight hours. All treated patients were discharged from the hospital on an average of thirteen days after beginning the treatment. The untreated controls remained on an average for 30.7 days after onset. No complications or deaths were noted with the 25 treated patients. Among the 12 untreated controls, in 2 complications developed (parotitis, pneumonia), and 1 died.

According to the daily press even more spectacular therapeutic effects were afterward obtained during an outbreak of epidemic typhus in Bolivia. Details are not yet reported.

THE AERO MEDICAL ASSOCIATION

The Aero Medical Association met at Royal York Hotel and R. C. A. F. Institute of Aviation Medicine, Toronto, Canada, June 16-18, 1948. Among the papers presented that of E. E. Poos, Detroit, pointed out that certain ocular symptoms, such as blurring, burning, light flashes, photophobia, vertigo, amaurosis fugax, disturbances of muscles, accommodation, convergence, migraine, glaucoma and central angiospastic retinopathy are frequently of psychosomatic origin, reflecting ocular symptoms of certain conversion syndromes. Among these may be mentioned guilt, conflict, fear, pain, indecisiveness, feelings of inferiority and fatigue reactions.

Ryan and his associates at the R. C. A. F. Institute of Aviation Medicine, Toronto, reported physiologic findings in normal men subjected to negative G.¹ The

outstanding symptoms under negative G and the limiting symptom by which the subject decides that his safe G tolerance is reached is pressure in the head region. Visual symptoms commonly include blurring, graying and more specifically reddening of vision. The pulse rate decreases under negative G and the greater the negative G the more pronounced the bradycardia. The pulse rate quickly increases again as the negative G decreases. On repeated negative tilts on six successive days men acquired a subjective tolerance for negative G, and the average pulse rate on the last negative tilts was significantly lower than on the first, suggesting a physiologic adaptation as the basis of this increased tolerance. A similar acquired tolerance was experienced on repeated exposures to the higher negative G values studied. Despite the absence of subjective cardiac symptoms, electrocardiograms from precordial leads showed increasing deviations from the normal with increasing negative G. These consisted of arrhythmias, prolonged P-R intervals, auriculoventricular heart block and bizarre QRS complexes, but most strikingly of periods of cardiac asystole (up to nine seconds' duration). Under the experimental conditions used it was demonstrated that healthy young men can with safety withstand 3 G negative for five seconds.

J. C. Douglas, of the University of Western Ontario, London, Canada, reported studies on pulmonary function with the use of the Milliken oximeter. He found that in normal subjects an alveolar oxygen tension of approximately 210 mm. of mercury produces complete saturation. This corresponds roughly to 35 per cent oxygen in the inspired air. The time to reach saturation is about forty seconds. In subjects with pulmonary dysfunction, significant differences in respect to both these measurements have been found. Henry and his associates at the Aero Medical Laboratory, Wright-Patterson Air Force Base, Dayton, Ohio, studied the effect of breathing high pressures on the circulation. The main effects were (1) the loss of plasma filtrate into the tissues and (2) pooling of blood with diminished venous return. Loss of fluid was estimated by means of hematocrit and hemoglobin determinations, and venous pooling by two methods: (1) a modification of the Evan's blue blood volume technic and (2) a water displacement plethysmograph. An immediate (first four minutes) effect of pressure breathing is pooling of approximately 7 per cent of total blood volume. A further loss of 10 per cent results from plasma filtration during a thirty minute period, making a total of approximately 15 to 20 per cent of total blood volume lost from effective circulation.

Haymaker and his co-workers reported on pathologic changes believed to have been due to hypoxia in 75 fatal cases of high altitude hypoxia. The pathologic changes were divided into three categories: (1) vascular phenomena including congestion, edema and hemorrhage; (2) vacuolar changes, with and without inclusion bodies, in parenchymal cells of various internal organs.

5. Smadel, J. E.; Woodward, T. E.; Ley, H. L., Jr.; Philips, C. B.; Traub, R.; Lewthwaite, R., and Savoor, S. R.: *Science* **108**: 160, 1948.

1. The terms "positive and negative G" are arbitrary ones used to designate the direction in which the G force is acting in relationship to the longitudinal axis of a human being. Positive "G" refers to "G" acting on the body in a direction from head to foot, while negative "G" refers to "G" acting in a direction from foot to head. The common sources of "G" are gravity, from which the term "G" is derived, and centrifugal force such as is encountered in flying.

and (3) reactive and degenerative changes in the central nervous system.

F. G. Hall, Duke University, Durham, N. C., presented an interesting study of various factors which affect the time interval between loss of oxygen and loss of useful consciousness in persons at simulated high altitudes. Factors investigated were barometric pressure, pulmonary ventilation, breathing pattern and composition of the blood. Striking differences occurred between individuals in useful consciousness times which appeared consistent from day to day but do not correlate with any factors so far studied. Smith and Law of University of Toronto made an interesting suggestion for meeting the emergency of sudden decompression of a pressurized passenger transport when flying at high altitude. The proposed method of meeting the emergency is to flood the cabin with oxygen gas, obtained by spraying liquid oxygen against a suitable evaporating surface. The weight of liquid oxygen required has been calculated, and is no greater than that of an emergency oxygen gas system. A safe breathing atmosphere can be produced within two minutes at 40,000 feet. If the aircraft promptly starts to descend, safety can be maintained in spite of a large outward leak.

W. R. Stovall, Civil Aeronautical Administration, Washington, D. C., stressed the responsibility of flight surgeons in the selection, welfare, health and safety of all flight personnel. The rapid growth of aeronautics calls for more flight surgeons; yet the number of surgeons is diminishing. Approximately 500 flight surgeons in the armed services, together with reservists in civilian practice, constitute the national pool. Several suggestions were made with the view of maintaining or increasing this pool.

Current Comment

"ANTIVIVISECTIONISTS HAVE NO VALID ARGUMENTS"

As predicted¹ when the antivivisectionists were exposed by the *Saturday Evening Post*,² the latter magazine was deluged with mail, some of which was commendatory, and some condemnatory. One antivivisectionist went so far as to threaten to use his rifle on experimenters. The *Post* publishes two columns of letters *pro* and *con*; one demands: "Answer yes or no. Are you or are you not going to print the other side of the vivisection question?" The following answer of the editors of the *Post* to this demand is significant: "We made an exhaustive study of the pros and cons of vivisection before we published 'They're Trifling with Your Life.' Not one valid argument in support of the antivivisectionist viewpoint was found. This being the case, we feel no obligation to publish anything more

than the comments in these columns."³ This ought to settle the antivivisectionist argument, but it will not. The antivivisectionists are not capable of being convinced, and continued vigilance by physicians and other scientists will be necessary. The antivivisectionists need constant watching even though they have not thus far achieved important legislative results.

ORIGIN OF PILONIDAL SINUS

A theory that most pilonidal sinuses are acquired infective and foreign body granulomatous reactions to buried hair rather than developmental malformations was recently proposed by Patey and Scarff.¹ They point out serious defects in the evidence for the developmental theory. A few sacrococcygeal dermoid cysts which are apparently developmental in origin unquestionably occur. They are located between the rectum and the coccyx; they are first noted in early life, and they are rarely infected. Pilonidal sinuses, on the other hand, are found chiefly in the intergluteal cleft; they first appear in young life, and they are almost invariably infected. About half of them contain hair; many have no epithelial lining; few show hair follicles in their walls, and fewer still show sebaceous glands. In the absence of these structures, there is no evidence for origin from dermoid. Postoperative recurrences may contain hair, yet have no epithelial cells. They may be so large that they could not have been left behind by an incomplete operation; they must have enlarged, probably under the influence of the hairs. The number of recurrences appears to be reduced by postoperative roentgen treatment. The suggestion is made that the role of such therapy may be to destroy the hair follicles. Finally, Patey and Scarff describe 3 examples of pilonidal sinus in the hands of barbers. These sinuses, except for their shorter length, resembled those in the postanal region. They contained hair which had apparently penetrated through the skin and set up a foreign body reaction, and there was no suspicion of preexisting dermoid. The authors suggest that a similar process might produce postanal pilonidal sinuses. The deeper penetration of the hair in both locations is attributed to the sucking action of negative pressures produced by passive motion of the adjacent tissues. This new theory is more attractive for explaining the pathogenesis of the pilonidal sinuses of the hand than of those in the postanal region. In the former, the hairs found in the sinus are short—a few millimeters. In the latter, they may be several centimeters long, indicating that they have grown. Therefore, they were attached and not free to migrate. The high incidence of a dimple in the postanal region of children at the location where the pilonidal sinus later develops indicates the presence of at least one type of malformation in these cases; so, presumably, there could be another. Finally, it is not clear why hair should penetrate and set up pilonidal sinuses only in the hand and the postanal region.

ORGANIZATION SECTION

World Medical Association

Second General Assembly, Geneva, Sept. 8-11, 1948

The World Medical Association held its Second General Assembly in Geneva, September 8 to 11. This important association includes practically all of the national medical organizations, thus constituting a world organization of physicians. The association aims to elevate medical ethics and the standard of medical education throughout the world. It hopes to defend the status of the physician against encroachment by the state, and to perfect medical organization and to make it more effective.

The 1948 General Assembly was to meet in Prague under the presidency of Professor Jaroslav Stuchlik. Recent political events in Czechoslovakia resulted in the dissolution of the Czechoslovakian Medical Association and in resignation of Dr. Stuchlik.

The General Assembly was opened on September 8 by M. Picot, President of the National Swiss Council. Dr. Routley of Canada, chairman of the Council of the World Medical Association, proposed that Professor Eugene Marquis of France be president of the association for the year 1948-1949.

Unified Medical Diploma

Several months ago Dr. L. H. Bauer (United States), general secretary, sent an inquiry to various national medical associations requesting their views concerning the establishment of a medical diploma which would be recognized in all of the countries of the world. This proposition was originated by Dr. Guy Dain of Great Britain. The majority of the countries felt that the idea was excellent but not practical. The assembly voted to abandon Dr. Dain's proposition.

The War Crimes of the German Doctors

At the previous assembly in Paris the World Medical Association solemnly condemned the crimes and the inhuman acts committed by the German physicians, and invited them to make a declaration which would recognize that a number of their colleagues "have violated the ethical traditions of medicine, defiled the professional medical honor and prostituted medical science by placing it at the service of war and political hatred." There is not now in Germany any national medical organization that could speak for the physicians of Germany.

The Hippocratic Oath

The inhuman acts perpetrated by certain physicians testified to the regrettable lowering of medical ethics. The World Medical Association believes that reestablishment of the original Hippocratic Oath or of its modern version to be read by the doctor on the receipt of his diploma would aid in impressing on him the fundamental principles of medical ethics and would tend to elevate the general level of professional practice. Dr. Cibrie (France) presented a convincing argument in favor of adoption of a modern version of the Oath. On motion of Dr. Pridham (England), seconded by the Danish delegate, the General Assembly adopted a motion that the name of the city of Geneva be included in the official text of the modified Hippocratic Oath. Following is the text of the Oath in French as formulated in Geneva with a proposed English text:

SERMENT D'HIPPOCRATE, FORMULE DE GENÈVE

Au moment d'être admis au nombre des membres de la profession médicale, je prends l'engagement solennel de consacrer ma vie au service de l'humanité.

Je garderai à mes maîtres le respect et la reconnaissance qui leur sont dus.

J'exercerai mon art avec conscience et dignité.

Je considérerai la santé de mon patient comme mon premier souci.

Je respecterai le secret de celui qui se sera confié à moi.

Je maintiendrai, dans toute la mesure de mes moyens, l'honneur et les nobles traditions de la profession médicale.

Mes collègues seront mes frères.

Je ne permettrai pas que des considérations de religion, de nation, de race, de parti ou de classe sociale viennent s'interposer entre mon devoir et mon patient.

Je garderai le respect absolu de la vie humaine, dès la conception.

Même sous la menace, je n'admettrai pas de faire usage de mes connaissances médicales contre les lois de l'humanité.

Je fais ces promesses solennellement, librement, sur l'honneur.

THE HIPPOCRATIC OATH FORMULATED AT GENEVA

Now being admitted to the profession of medicine I solemnly pledge to consecrate my life to the service of humanity. I will give respect and gratitude to my deserving teachers. I will practice medicine with conscience and dignity. The health and life of my patient will be my first consideration. I will hold in confidence all that my patient confides in me. I will maintain the honor and the noble traditions of the medical profession. My colleagues will be as my brothers. I will not permit considerations of race, religion, nationality, party politics or social standing to intervene between my duty and my patient. I will maintain the utmost respect for human life from the time of its conception. Even under threat I will not use my knowledge contrary to the laws of humanity. These promises I make freely and upon my honor.

The Bulletin of the World Medical Association

Dr. Charles Hill, secretary of the British Medical Association, presented a well documented report on the subject of creating a bulletin of the World Medical Association. The bulletin will appear four times annually, will contain a résumé of the papers presented at the Council and at the General Assembly, and will report on subjects of medicosocial nature. Dr. Routley (Canada), President of the Council, announced that Dr. Morris Fishbein (Chicago), the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, is to be the chief editor of the bulletin.

Relations with Other International Organizations

The World Medical Association intends to maintain most cordial relations with the great international organizations, in particular with the World Health Organization and with UNESCO. The World Medical Association has appointed two permanent observers whose duty will be to report on the activities of these organizations. Dr. Maystre (Geneva), president of the Medical Association of Geneva, will report on the international organizations' meeting in Geneva; Dr. Cibrie (Paris), recording secretary of the World Medical Association for Europe, will report the discussions of the UNESCO. Dr. Calderone of New York, replacing Dr. Chisolm, has reported the aims of these great organizations and presented in an extensive table the activities and the aims of the World Health Organization.

Coming Meetings of the World Medical Association

The General Assembly decided to hold the 1949 meeting in London; the 1950 meeting in the United States, city not designated; and the 1951 meeting in Stockholm. In case of inability on the part of any of these nations to serve as the meeting place, Spain will be ready to receive the delegates.

Discussion of the Subject of Social Insurance

Social insurance is in process of expansion almost everywhere, and particularly in Europe. The International Association for Social Security and the International Labour Organization appear to be resolved to encourage a complete program of social insurance, embracing medical service for the entire world. The Council of the World Medical Association recommended

to the General Assembly at Geneva the initiation of an extensive inquiry, detailed and precise, to be reported on by the national medical associations with the view of arriving at correct information on the status of the subject in each country. A permanent committee on social insurance was appointed by the General Assembly. This committee will make every effort that doctors be not outdistanced in the matter of social security by the International Conference, which carries on its work on a permanent scale. It is a matter of regret that because of lack of organization doctors always find themselves faced with accomplished facts when it is too late to suggest and to bring about modifications of decisions already taken.

Several delegates presented in the course of discussion upon this subject rather general ideas for social insurance schemes in their respective countries

Recommendations

The following resolutions were adopted at the General Assembly in Geneva as fundamental in any system of social security.

- a. Freedom of choice of physician by the patient. Liberty of physician to choose patient except in cases of urgency or humanitarianism.
- b. No intervention of third party between physician and patient.
- c. Where medical service is to be submitted to control, this control should be exercised by physicians.
- d. Freedom of choice of hospital by patient.
- e. Freedom of the physician to choose the location and type of his practice.
- f. No restriction of medication or mode of treatment by physician except in case of abuse.
- g. Appropriate representation of medical profession in every official body dealing with medical care.
- h. It is not in the public interest that physicians should be full time salaried servants of the government or Social Security bodies.
- i. Remuneration of medical services ought not to depend directly on the financial condition of the insurance organization.
- j. Any Social Security or insurance plan must be open to the participation of any licensed physician, and no physician should be compelled to participate if he does not wish to do so.
- k. Compulsory health insurance plans should cover only those persons who are unable to make their own arrangements for medical care.
- l. There shall be no exploitation of the physician, the physician's services or the public by any person or organization.

World Medical Association and Scientific Research

In Canada, in the United States of America and in England are councils of medical research. The Assembly decided to request the most immediate and extensive diffusion possible of the results of these researches.

The Question of Refugee Doctors

The General Assembly listened to a communication of Dr. Coigney, Medical Advisor of the International Organization of Refugees in Geneva. Among the total of 800,000 "displaced persons" there are about 3,000 doctors between the ages of 25 and 45 years. Dr. Coigney requested the assembly to propose to various governments to pass definite laws to authorize these doctors to practice their arts after having passed examinations and after having obtained naturalization. The speaker invoked the seventh paragraph of the Hippocratic Oath adopted by the assembly. In the name of the Council, Dr. Routley emphasized the importance of the question and proposed to submit it at the next meeting of the Council.

The Council of the World Medical Association endorsed the efforts of the A.S.E.M. ("Swiss Aid to the Children of the Doctors, Victims of the War") whose office is in Geneva, and has decided to support this work so far as is possible.

The Newly Elected President

Dr. Charles Hill, honorary secretary of the British Medical Association, who has done so much for the organization of the World Medical Association, was elected by acclamation president for 1949.

Washington Letter

(From a Special Correspondent)

Oct. 7, 1948.

Displaced Professional Persons

According to the International Refugee Organization, which has headquarters in Washington, there are now 30,437 professional men and women in European D.P. camps who meet preferential requirements fixed by Congress in the Displaced Persons Act of 1948. Of this number, 1,150 are listed as physicians or surgeons. Nurses number 2,566, although complete information on the percentage of these who are registered is not available.

Volume on "America's Health"

One week after Washington offices of National Health Assembly had sent a letter to 4,200 individuals and representatives of organizations active in the public health field, 500 replies were received expressing interest in procurement of "America's Health: A Report to the Nation." This is the provisional title of the prospective volume which will present the findings of the fourteen sections participating in the National Health Assembly held here last May. According to the answers on the reply card, a 500 page volume priced at \$5 is preferred over 200 pages at \$4 or 600 to 700 pages at \$5.50 to \$6.50. The first week's 500 respondents indicated that they would be interested in purchasing a total of 2,500 copies. The volume, the fourteen sections of which are in the editing stage, is scheduled to appear between spring and fall of 1949.

Research a Challenge

Dr. Leonard A. Scheele, Surgeon General, U. S. Public Health Service, addressed the opening of the one hundred and twenty-fifth session of George Washington University School of Medicine September 20. Medical research, preventive medicine and psychiatry were singled out by Dr. Scheele as specialties in which too few students are interested. He said, "There is no greater challenge to intellectual and social pioneering in our age than research and preventive medicine. The shortages of medical investigators and medical health officers are acute, not only in the programs of the Public Health Service, but in research institutions and health departments all over the country." Dr. Scheele noted that ten graduates of George Washington University School of Medicine are now serving in the commissioned corps of Public Health Service.

Blood Plasma Distributed in Palestine

American Red Cross headquarters here has been informed that dried blood plasma donated for use in Palestine has been distributed to six principal cities. Shipped to the Middle East last July, the plasma is part of more than \$500,000 worth of medical and relief supplies donated by the American Red Cross for Jewish and Arab victims of the Palestine conflict. Nazareth, Gaza, Jerusalem, Tel Aviv, Ramallah and Jericho are the cities to which the plasma was sent, under supervision of International Red Cross. Meantime, the American Red Cross is sending two ambulances to the Syrian Red Crescent to aid Arab and Jewish refugees in Syria.

New Veterans Administration Hospital at Houston

The Army Corps of Engineers has issued invitations for bids to construct a thousand bed Veterans Administration neuropsychiatric hospital to be erected at Houston, Texas. Bids are scheduled to be opened October 21 at the District Engineer's Office, Galveston.

GOVERNMENT SERVICES

NAVY

NEW REGULAR OFFICERS

The following reserve officers have been transferred to the Medical Corps of the Regular Navy: Comdr. Thomas P. Rogers, Indianapolis; Lieut. (jg) David G. Dixon, Homestead, Pa.; Lieut. (jg) Martin D. Greaney Jr., Los Angeles; Lieut. (jg) Frank P. Hammon, Saratoga, Calif., and Lieut. (jg) Henry A. Schlang, Flushing, N. Y.

RESERVE OFFICERS ON ACTIVE DUTY

The following inactive reserve medical officers have been recalled to active duty: Lieut. Comdr. Alexander A. Bolton Jr., Lake Mohawk, Sparta, N. J.; Lieut. Comdr. William W. Manson, Sidney, N. Y.; Lieut. Gustave T. Anderson, North Platte, Neb.; Lieut. Trowbridge H. Mafit, Chicago; Lieut. (jg) Hodge M. Eagleson, Pittsburgh; Lieut. (jg) William S. Foutz, Cleveland; Lieut. (jg) Albert M. Jenkins, Norwood, Ohio, and Lieut. (jg) Francis X. MacAulay, Westminster, Mass.

The following lieutenants (jg) of the Medical Reserve Corps have received orders to report for their first active duty:

Armon A. Cairo, Steelton, Pa., to Georgetown University Hospital, Washington, for duty as intern.

Leon W. Clark, Houston, Texas, to University of Texas Hospitals, Galveston, Texas, for instruction in pediatrics.

Myron E. Erickson, Minneapolis, to Swedish Hospital, Minneapolis, for duty as intern.

Alfred K. Hawkes, New Orleans, to Tulane University of Louisiana School of Graduate Medicine, New Orleans, for instruction in otolaryngology.

Theo. N. Kirkland Jr., Montgomery, Ala., to Tulane University of Louisiana School of Graduate Medicine, New Orleans, for instruction in ophthalmology.

Charles E. Mangin, Biloxi, Miss., to Touro Infirmary, New Orleans, for instruction in pediatrics.

Harry L. Roberts Jr., Hanover, N. H., to Columbia Hospital for Women, Washington, D. C., for instruction in obstetrics and gynecology.

Paul E. Rockwell, Brooklyn, to the Administrative Command, Great Lakes, Ill., for duty in the Medical Department.

William R. Sillery, Cliffside Park, N. J., to Long Island College Hospital, Brooklyn, for instruction in obstetrics and gynecology.

Robert R. Wadlund, Wethersfield, Conn., to the Naval Hospital, St. Albans, N. Y.

POSTGRADUATE INSTRUCTION

The following officers of the Regular Navy have been nominated for courses of postgraduate instruction: Comdr. Ross P. Black, urology; Comdr. James A. Fields, otolaryngology; Comdr. Joseph A. Force, internal medicine, all at the University of Pennsylvania Graduate School of Medicine, Philadelphia; Comdr. Richard D. Nies, psychiatry, Naval Hospital, Bethesda, Md.; Comdr. Nelse O. Olson, ophthalmology, Washington University School of Medicine, St. Louis; Comdr. Joseph J. Timmes, surgery, University of Pennsylvania Graduate School of Medicine, Philadelphia; Lieut. Comdr. Wilbur S. Lummis Jr., internal medicine, Northwestern University Medical School, Passavant Hospital, Chicago; Lieuts. Don L. Andrus, surgery, University of Pennsylvania Graduate School of Medicine, Philadelphia; Edward L. Beckman, electroencephalography and neurophysiology, Naval Hospital, Bethesda, Md.; Berwyn R. Force, internal medicine, University of Pennsylvania Graduate School of Medicine, Philadelphia; Emil P. Thelen, fellowship in neurosurgery, Mayo Clinic, Rochester, Minn.; Frank H. Thomas Jr., internal medicine, University of Pennsylvania Graduate School of Medicine, Philadelphia, and Henry G. Wagner, ophthalmology, University of Pennsylvania Graduate School of Medicine, Philadelphia; Lieuts. (jg) John G. Esswein, residency in internal medicine, Naval Hospital, Philadelphia; Aubrey D. Bantt, Submarine School, New London, Conn.; Clarence H. Johnston, residency in pathology, Naval Hospital, San Diego, Calif., and Vincent E. Lowery, residency in psy-

chiatry, Naval Hospital, Bethesda, Md. Comdrs. James G. Bulgrin, residency in radiology, Naval Medical Center, Bethesda, Md.; John L. Flannery, instruction in pediatrics, University of Pennsylvania Graduate School of Medicine, Philadelphia; William S. Francis, residency in internal medicine, Naval Hospital, Oakland, Calif., and Jesse F. Richardson, fellowship in urology, Washington University Medical School; Lieut. Comdr. Byron E. Bassham, fellowship in surgery, Lahey Clinic, Boston; Lieuts. (jg) Winton R. Boyd, residency in obstetrics and gynecology, Naval Hospital, Oakland, Calif.; Carl A. Broadbush Jr., residency in surgery, Naval Hospital, Oakland, Calif.; Harold A. Davis, MCR, residency in internal medicine, Naval Hospital, San Diego, Calif., and Andrew M. Margileth, residency in pediatrics, Naval Hospital, National Naval Medical Center, Bethesda, Md.

WOMEN IN THE NAVY MEDICAL CORPS

Among the first 288 women officers who have been selected for commissions in the Regular Navy under the provisions of the Women's Armed Services Integration Act of 1948 are 2 in the Medical Corps, 21 in the Medical Service Corps and 1 chief warrant officer in the Hospital Corps. The 2 in the Medical Corps are Lieutenant Commander Frances Lois Willoughby of Washington, D. C., a graduate of the University of Arkansas School of Medicine, Little Rock, and Lieutenant Gioconda Rita Saraniero of Brooklyn, a graduate of Women's Medical College of Pennsylvania, Philadelphia.

INTERNS AT CIVILIAN INSTITUTIONS

The Bureau of Medicine and Surgery of the Navy announces the following Naval Medical Reserve Corps officers who have received their first orders for active duty as interns in civilian institutions under the new medical training program:

Lieut. (jg) James E. Fitzgerald, Chevy Chase, Md., to Gallinger Municipal Hospital, Washington, D. C.

Lieut. (jg) James R. Martin, Pittsburgh, to Allegheny General Hospital, Pittsburgh.

Lieut. (jg) Victor A. Moore Jr., Roswell, Ga., to University Hospital, Augusta, Ga.

Lieut. (jg) Joseph H. Pritchett Jr., Decatur, Ga., to University Hospital, Augusta, Ga.

Lieut. (jg) Rob J. Rutledge, Oklahoma City, to Kansas City General Hospital, Kansas City, Mo.

Lieut. (jg) Theodore Safford Jr., Wyoming, Ohio, to Lenox Hill, N. Y.

Lieut. (jg) Emmitt H. Shoemaker, Houston, Texas, to Hermann Hospital, Houston, Texas.

Lieut. (jg) Frank F. Stangl, Gallup, N. M., to Kansas City General Hospital, Kansas City, Mo.

AWARDS AND COMMENDATIONS

Commander John E. Nardini

The commanding general of the Philippine Coast Artillery Command awarded in April, 1942, the Silver Star to then Lieut. John E. Nardini of Philadelphia. The citation read as follows:

"For gallantry in action at Fort Mills, Philippine Islands, March 30, 1942. During the course of a combined enemy aerial and artillery bombardment of Fort Mills, Lieutenant Nardini, together with Pharmacist's Mate Second Class Donald E. Bansley, 2124309, U. S. Navy, without regard for his personal safety and while enemy planes were overhead, voluntarily left a place of shelter and evacuated a Marine who had been seriously wounded by shell fragments to Malinta Hospital. Dr. Nardini graduated from Temple University School of Medicine, Philadelphia, in 1938 and entered the Navy on July 18 of that year."

VETERANS ADMINISTRATION

NON-SERVICE-CONNECTED DISABILITIES

In a summary of its activities as of Aug. 31, 1948, the Veterans Administration reported a total of 105,048 patients in hospitals; of the 92,983 in Veterans Administration hospitals 61,091 were veterans with non-service-connected disabilities; of the 12,065 patients not in Veterans Administration hospitals, 7,488 were veterans with non-service-connected disabilities. In addition there were 14,342 beneficiaries in Veterans Administration homes.

Eighty-nine new hospitals were in progress at the end of August, of which the construction contracts had been awarded for 28, the designs were in progress in 50, the designs not started in 3 and the designs completed but construction contracts not awarded in 8. Through the end of the month, 63 sites have been acquired for new veterans hospitals, 20 specific sites have been approved but not acquired, 7 specific sites were in the process of selection; furthermore, 31 additions and conversions to the hospital addition and conversion program had been completed throughout the month and seventeen other additions and conversions were in progress.

At the end of August, 18,560 veterans were awaiting hospital admission; of these 18,490 had disabilities adjudicated non-service-connected; 77,277 applications for hospital or domiciliary care were received through the month, and 33,679 applications were filed for automobiles for disabled veterans.

COURSE IN REHABILITATION

Nineteen physicians from various Veterans Administration hospitals and one Army physician are enrolled in the second 3 month course of instruction in physical medicine and rehabilitation, which will continue until December 11 at the Veterans Administration Hospital, Hines, Ill. The course is under the direction of Dr. Louis B. Newman, chief of physical medicine rehabilitation service. This group visited the A. M. A. headquarters September 29 and was addressed by the directors of various departments.

PUBLIC HEALTH SERVICE

CONFERENCE ON GASTRIC CANCER

The National Advisory Cancer Council has called a conference on gastric cancer to be held in San Francisco December 13-14 to review research progress in this field and attempt to give direction to the development of methods of diagnosis and treatment. At one evening session of the conference, the scientists will meet with physicians of the San Francisco Bay area to discuss the clinical applications of their findings. Dr. Leonard A. Scheele, Surgeon General of the Public Health Service and chairman of the Council, said that according to official mortality records gastric cancer causes about 45 per cent of all deaths due to cancer and that the reason undoubtedly is the silent nature of the disease. "It is almost impossible," he said, "to diagnose gastric cancer in its early stages when cure might be expected."

The Public Health Service has made previous attacks on the problem of gastric cancer, having had in effect for years a program of grants-in-aid specifically planned to develop research on gastric cancer. Altogether, twenty-three grants totaling \$261,424 are being devoted to research on such problems as the relation between gastric cancer and diet, the possible influence of hormones on gastric cancer and the role, if any, that pernicious anemia and ulcers play.

NEW DIRECTOR OF INDIAN HEALTH

The Surgeon General announces the appointment of Dr. Fred T. Foard as Director of Health at the Bureau of Indian Affairs of the Department of the Interior. Dr. Foard was graduated from University of Maryland Medical School and is a medical director in the United States Public Health Service.

NEW HOSPITAL AT ERIE, PA.

Ground breaking ceremonies were held in June marking the beginning of construction of the two hundred bed veterans general hospital at Erie, Pa., on the southwest corner of Old French Road and East 38th Street Boulevard. Among those

New Veterans Hospital at Erie, Pa.

taking part in the ceremony were Dr. Guy C. Boughton, representing the Erie County Medical Society; Capt. Henrietta Dorris, Army Nurse Corps; Dr. Joseph Galbo, representing the American Legion and Dr. Elmer Hess.

PERSONALS

Dr. J. Haywood Davis has been assigned as chief medical officer of the Veterans Administration Outpatient Clinic at Fort Worth, Texas, succeeding Dr. M. D. Badt.

Dr. Thomas J. Ready has been assigned as chief medical officer and Dr. Frank D. Thomas as chief of the outpatient medical service for the Pass-a-Grille regional area in Florida. Dr. Ready is a graduate of Georgetown University School of Medicine, Washington, D. C., and served in the Army Medical Corps during the recent war. Dr. Thomas is a graduate of Hahnemann Medical College, Philadelphia, and is a veteran of World War I.

DR. GILLIAM TO HEAD EPIDEMIOLOGY SECTION

Dr. Alexander G. Gilliam of the regular Army Medical Corps has been appointed by the Surgeon General to head the Epidemiology Section of the Cancer Control Branch, National Cancer Institute, which section was recently formed to improve information on cancer incidence and mortality. For two years Dr. Gilliam has been detailed to the University of Michigan School of Health, where he conducted studies on poliomyelitis and taught in the Department of Epidemiology. During the war he was epidemiologist to the United States of America Typhus Commission and was awarded the Typhus Medal for conducting typhus surveys among United States troops in Egypt, Tripoli, China, Burma and India.

CANCER RESEARCH GRANTS

The Federal Security Administrator announced September 26 National Cancer Institute grants of more than \$1,300,000 to finance cancer control and research work in institutions in twenty-six states, the District of Columbia, Puerto Rico, Canada and France. These grants were first approved by the National Advisory Cancer Council and by the Surgeon General of the Public Health Service at a meeting of the council a few days previously. Twelve grants totaling \$186,114 were made for such special projects as the development of laboratory diagnostic tests for cancer, surveys of occupational cancer and training in cytologic test techniques. More than one hundred medical and dental schools have qualified for financial aid since the beginning of the program of the Public Health Service less than a year ago.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest; such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CONNECTICUT

Yale University Retirements.—Retirement of three faculty members of Yale University School of Medicine, New Haven, has been announced: Dr. Arthur H. Morse, former chairman of the department of obstetrics and gynecology; Dr. George M. Smith, research associate in anatomy with the rank of professor, and Miss Alice M. Hunt, assistant professor of anesthesia. Dr. Morse, who has been departmental chairman and obstetrician and gynecologist in chief of the New Haven Unit of the Grace-New Haven Community Hospital since 1921, became assistant professor of obstetrics and gynecology at Yale in 1915 and received a promotion to clinical professor in 1920 and to professor in 1921. Dr. Smith has held the post of research associate with the rank of professor at Yale since 1936. He has been medical director of the Anna Fuller Fund, which provides research grants for investigating problems of cancer, since 1933. He is also a member of the board of scientific advisers of the Jane Coffin Childs Memorial Fund for Medical Research and is executive director of the National Advisory Cancer Council. Miss Hunt was instructor in anesthesia at Yale from 1922 to 1930 and since that time has been an assistant professor of anesthesia and anesthetist for the New Haven Unit of the Grace-New Haven Community Hospital.

FLORIDA

Cancer Seminar.—The Cancer Seminar of the Southeastern States will be held November 8-10, at the Tampa Terrace Hotel, Tampa, under the direction of the Tumor Clinic, Tampa Municipal Hospital, and sponsored by the American Cancer Society, Florida Division, and the Florida State Board of Health. The seminar will consist of morning and afternoon sessions, presenting in panel discussion carcinoma of the breast, the lung, the uterus, the ovary and the stomach. Each subject will be discussed by a surgeon or internist, a pathologist and a roentgenologist. At the end of each panel discussion thirty minutes will be allowed for questions from the audience. This seminar is conducted for the doctors of the Southeastern states and is primarily intended for the benefit of physicians in general practice; however, specialists in any field of medicine are urged to attend. Requests for hotel accommodations should be sent to Mr. A. K. Dickinson, % Tampa Chamber of Commerce, Tampa, Fla.

GEORGIA

Narcotic Violation.—The Federal Bureau of Narcotics reports that Dr. Joseph Haskell Hudson, Gough, pleaded guilty at Savannah to violation of the federal narcotic law and on May 11 was placed on probation for a period of three years.

Courses in Diagnosis of Rabies.—The Public Health Service Communicable Disease Center at Atlanta will offer a course in the laboratory diagnosis of rabies December 6-10, open to all grades of employed laboratory personnel. There is no tuition or laboratory fee, but traveling and living expenses must be paid by the individual or his employer. Applications should be made to Ernest S. Tierkel, 605 Volunteer Building, Atlanta 3, Ga.

ILLINOIS

First Medical Students' Loans.—Three premedical students have received loans of \$5,000 to finance their medical education under the \$100,000 joint medical student loan fund set up by Illinois Agricultural Association and the Illinois State Medical Society. The students and the universities which they will attend are: Burton E. Bagby of Mounds, Loyola University Stritch College of Medicine, Chicago; L. C. Fiene of Sparta and Lawrence Irish of Blandensville, the University of Illinois. Men from rural communities who have completed premedical courses, who are approved by local farm bureaus and medical societies and who will agree to practice in rural communities are eligible for \$5,000 loans at the rate of \$1,000 a year to complete their four year medical courses and one year internships. A list of twenty priority counties, where the situation is worse than usual, has been set up for Illinois. All three candidates are from such counties. The scholarship loan plan for medical training was established late in 1947 (THE JOURNAL January 1, page 48).

Chicago

Belfield Memorial Lecture.—The Chicago Urological Society at its meeting October 21 will hear the annual William T. Belfield Memorial Lecture, by Dr. Charles P. Mathe of San Francisco on "Operative Interventions on the Solitary Kidney." All society meetings for the year will be held in the Congress Hotel.

Symposium on Medicolegal Problems.—A symposium on Medico-Legal Problems will be held on Tuesday evenings at 7:30 October 26 through November 23 and on December 2 at the Chicago Bar Association. The programs, under the sponsorship of the Institute of Medicine of Chicago, the Chicago Medical Society and the Chicago Bar Association, are as follows:

Oct. 26, Mental and Chronological Age Problems in Law and Medicine: Medical Presentation, David Shakow, Ph.D., Chicago; Legal Presentation, Hon. Joseph J. Drucker, Chicago.

Nov. 2, Sex Offenses and Sex Offenders: Medical Presentation, Harry R. Hoffman, Chicago; Legal Presentation, Erwin W. Roemer, Esq., Chicago.

Nov. 9, Modern Methods of Crime Detection: Medical Presentation, Roy R. Grinker and Mr. Leonard Keeler, Chicago; Legal Presentation, Fred E. Inbau, Esq., Chicago.

Nov. 16, Income Tax Discrimination Against the Professions: Medical Presentation, Frank G. Dickinson, Ph.D., Chicago; Legal Presentation, Robert F. Spindell, Esq., Chicago.

Nov. 23, Problems of Alcoholism from the Medical and Industrial Aspects: Medical Presentation, Andrew C. Ivy, Chicago; Industrial Aspects: Edward C. Holmblad, Chicago; Legal Presentation, James J. McKenna, Esq., Chicago.

Dec. 2, How Can the Constitutional Office of Coroner Serve Modern Needs: Medical Presentation, Herbert S. Breyfogle, Richmond, Va.; Legal Presentation, Francis X. Busch, Esq., Chicago.

New Radio Health Series.—The Chicago Industrial Health Association will inaugurate its radio health series, entitled "It's Your Life," on October 18, at 11:15 to 11:30 a. m. over station WMAQ. The program, sponsored by Johnson and Johnson, will provide stories of better living through authentic tape-recorded interviews with anonymous Chicagoans. The plan is to include all phases of personal, family, community and industrial health. About 300 of Chicago's health and welfare agencies will aid with the planning and production of the programs. Broadcasts will be outlined by the association's radio advisory committee, composed of medical authorities, and will be completely reviewed by the committee and the educational committee of the Illinois State Medical Society. The Chicago Industrial Health Association was organized last January as a joint undertaking by the city officials and voluntary health and medical agencies, business and labor organizations and industrial and commercial firms. It is planning an extended program to include the community as a whole through the following health services: a health and social welfare referral service for employees, a monthly news letter to management, health agency surveys and services for industry, and a panel of leading industrial physicians and surgeons to assist firm medical departments.

Dr. Miller Elected President of Northwestern University.—Dr. J. Roscoe Miller, dean of Northwestern University Medical School, has been elected president of Northwestern University and will assume office July 1, 1949. He succeeds Franklin B. Snyder, who will retire Sept. 1, 1949. Dr. Miller will be the twelfth president of the university. Dr. John Evans, the founder and first president of the university, also was a physician and medical educator. Dr. Miller, a native of Utah, has been a member of the teaching staff of Northwestern University Medical School since 1930, in which year he received his M.D. degree from Northwestern. He served as assistant dean of the school from 1933 until his appointment as dean in 1941. During World War II he was a commander in the Medical Corps, U. S. Navy, in charge of the section on internal medicine of the Professional Division, Bureau of Medicine and Surgery, Washington, D. C. Dr. Miller is now president of the Chicago Medical Society, president elect of the Association of American Medical Colleges, a trustee of Wesley Memorial and Passavant Memorial and Evanston hospitals, and a member of numerous medical societies and associations. Under his able guidance during the past seven years the medical school has made outstanding progress in teaching and research and has increased its facilities and assets.

INDIANA

State Association News Letter.—The first issue of the Indiana State Medical Association's monthly *News Letter* was published in August as a supplement to the journal. It will be sent to all members of the state association.

Dr. Huber to Head Department.—Dr. Carl P. Huber, associate professor of obstetrics and gynecology, Indiana University School of Medicine, Bloomington-Indianapolis, was made professor and chairman of the new department of obstetrics and gynecology at the university August 1. Dr. Huber is a graduate

of the University of Michigan Medical School, Ann Arbor, 1928. He has been a staff member of the medical school and university hospitals at the medical center for nearly ten years. He also serves as consultant in obstetrics to the Indiana State Board of Health.

KANSAS

Society News.—At a meeting June 19 in Wichita, the Kansas Psychiatric Society chose Dr. Jesse F. Casey, Topeka, as president, and Dr. Frank F. Merker, Topeka, secretary-treasurer.

Postgraduate Course.—Meminger Foundation School of Psychiatry and the Winter Veterans Administration Hospital in Topeka are accepting applications for admission to the school on Jan. 1, 1949, available only to doctors who have had some psychiatric residency training in an approved hospital and who can therefore qualify for advanced standing. Those accepted will be placed in the class which entered July 1, 1948. Application should be made to Dr. Bert Boothe, Director of Professional Education, Winter VA Hospital, Topeka, Kansas.

MASSACHUSETTS

Public Health Forums at Harvard.—The second Public Health Forum of the Harvard University School of Public Health will be held at the school October 14 at 3:30 p. m. Dr. James R. Miller, Hartford, Conn., member of the executive committee of the Board of Trustees of the American Medical Association, will speak on "Opportunities Presented by the Development of National Health Program for the Public Health Profession and Private Practitioners of Medicine to Coordinate Their Activities in the Public Interest." The third forum speaker, Dr. Morris Fishbein, Editor of THE JOURNAL, will speak on November 16, at 3:30 p. m., on "Trends in Social Security."

Personals.—Dr. Harlan L. Paine, North Grafton, resigned as superintendent of the Grafton State Hospital, September 15, after completing twenty-seven years' service, to assume the superintendency of the Channing Sanitarium, Inc., in Wellesley. Dr. Paine served the department of mental health of the Commonwealth of Massachusetts for thirty-nine years.—Boston University School of Medicine has appointed Colonel Charles B. Perkins, Medical Corps, United States Army, as instructor of Army medical and military science and professor of radiology. Colonel Perkins is now serving as a resident in radiology at Massachusetts Memorial Hospitals under Dr. George Levene, chief of radiology.

MICHIGAN

The Biddle Lecture.—Dr. Edward A. Strecker, professor of psychiatry at the University of Pennsylvania School of Medicine, Philadelphia, presented the Biddle Lecture at the annual session of the Michigan State Medical Society September 22, on "Compromise or Chaos."

Hearing Consultants Service.—Schools in fifty counties have requested the service of the Michigan Department of Health's two hearing consultants this year. More than 250,000 children have been examined for hearing loss since the department's program began in 1943. Of the 3 per cent showing some hearing loss, about 50 per cent improved to normal hearing, according to the state department of health.

Survey of Premature Babies' Deaths.—The Bureau of Maternal and Child Health of the Michigan Department of Health is conducting a survey of the causes of death of babies born prematurely and is urging all expectant mothers to get early medical care. The bureau estimates that 8,000 premature infants were born in Michigan last year and, according to the death certificates, more than half of the 5,120 infant deaths were from causes related to prematurity. Pamphlets to aid the expectant mother may be obtained from local health departments or from the Michigan Department of Health, Lansing 4.

MINNESOTA

Receives Hospital Association Award.—Mr. James A. Hamilton, director of the hospital administration course at the University of Minnesota, Minneapolis, received the Award of Merit of the American Hospital Association for many years of leadership and activity in behalf of hospitals and the association. The award was conferred at the association meeting in Atlantic City, N. J., September 20-23.

Clinical Conference.—The Fall Clinical Conference of the Wells County Medical Society was conducted at the Bluffton Country Club September 15. Guest speakers were:

Fred L. Adair, Chicago, Toxemias of Pregnancy.
Archibald L. Hoyne, Chicago, Poliomyelitis Problems.
Frederick B. Wishard, Anderson, Ind., Routine Chest Surveys in Industry.
James O. Ritchey, Indianapolis, Ind., Dyspnoea of Cardiac Origin.

NEW YORK

Historical Portrait.—The Westchester County Medical Society has been presented an oil portrait of one of its early members, Dr. Isaac G. Graham, who was an assistant surgeon in the American army during the Revolutionary War and served under General Washington at West Point. The portrait was presented to the society by Mrs. F. Worden M. Graham, Washington, D. C., at the wish of her recently deceased husband, a great grandson of Dr. Isaac Graham. Dr. Isaac Graham began his medical practice in Unionville (now Hawthorne) in 1784 and continued in active practice for over half a century. He died September 1848, aged 88.

Postgraduate Instruction.—The Medical Society of the State of New York with the cooperation of the New York State Department of Health has arranged the following postgraduate lectures: The Richmond County Medical Society meeting at the Old Mill, Staten Island, November 10, at 9:30 p. m., will hear Dr. Howard C. Taylor Jr., New York, speak on "Physiologic Studies of Toxemia of Pregnancy." On December 8 they will hear a symposium on "Heart Disease and Pregnancy" given by two Brooklyn doctors, Edwin P. Maynard Jr. and Thornton Wallace. On November 2 Dr. George P. Heckel, Rochester, will speak on "Practical Application of Endocrines in Gynecology" before the members of the Schenectady County Medical Society, meeting in the auditorium of the Eastern New York Orthopedic Hospital, Schenectady, at 8:30 p. m.

New York City

Dr. Snyder to Direct Clinic.—Dr. Joseph E. Snyder has been named director of the Vanderbilt Clinic, the outpatient department for the voluntary hospitals of the Columbia-Presbyterian Medical Center, and administrative assistant in charge of the Columbia-Presbyterian Medical Center and of professional services to patients at the clinic. Dr. Snyder is a graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1943.

Personals.—Dr. Martin R. Steinberg, assistant director since 1945, has been appointed director of Mount Sinai Hospital of New York, succeeding Dr. Joseph Turner, who has been named consultant to the Board of Trustees.—Dr. Edward L. Howes, associate clinical professor of surgery, Columbia University College of Physicians and Surgeons, was recently made an honorary member of the Piedmont Surgical Society of Northern Italy.

Reading Program for Mentally Ill.—Columbia University's School of Library Science is conducting a study "to develop the basic types of reading programs" that may aid mentally ill patients. A special internship has been established at a state hospital in the metropolitan area and a qualified graduate librarian is working under the direction of the hospital. A course entitled "library work with hospital patients" has been established to aid this work. The program is designed to determine whether rehabilitation is stimulated or retarded through planned reading programs.

OHIO

University Retirements.—Dr. Arthur H. Bill, Cleveland, retired in June as head of the obstetrical department of Western Reserve University School of Medicine. He expects to continue his private practice. Dr. Morse F. Osborn, a member of the Ohio State University College of Medicine Student Health Staff, Columbus, for twenty years, retired this summer.

Dr. Alter Goes to Beirut.—Dr. Robert L. Alter, Toledo, will assume duties in October as professor and head of the department of obstetrics and gynecology at American University in Beirut, medical center of the Near East. En route he will lecture in Munich, Germany, before displaced doctors in a program arranged by the International Refugee Organization, a branch of the United Nations. Dr. Alter received his medical degree in 1937 from Duke University School of Medicine, Durham, N. C., where he later became an instructor in obstetrics and gynecology. In 1946 he moved to Toledo, where he engaged in private practice.

PENNSYLVANIA

Personal.—Dr. John B. F. Wyant has resigned as medical examiner in Kittanning and rural public schools after having served nearly sixty years. The school directors, on accepting his resignation, named him a lifetime honorary physician of the local school district.

Graduate Course in Cancer.—The School of Medicine of the University of Pennsylvania, Philadelphia, will present three courses this year in the diagnosis and treatment of cancer for physicians, under a grant from the State Department of Health. The first course will extend from November 8 to 20; the second

from January 17 to 29, 1949, and the third, April 25 to May 6, 1949. The courses are limited to small groups. Application must be received not later than four weeks before the opening date of the courses applied for. Application blanks will be sent on request to Dr. Robert C. Horn, Secretary of the Cancer Commission, Hospital of the University of Pennsylvania, Philadelphia 4. Tuition fees and some compensation for time spent away from regular practice will be paid by the Division of Cancer Control of the State Health Department.

Pittsburgh

Dr. Parran to Head New School of Public Health.—A new graduate school of public health is being set up at the University of Pittsburgh through a \$13,600,000 grant from the A. W. Mellon Educational and Charitable Trust. The first dean of the new school will be Dr. Thomas Parran, former Surgeon General of the United States. The school will emphasize occupational and industrial health and hygiene and do basic research in all phases of public health. It is expected that the school will begin operation by the fall of 1949. An initial \$4,000,000 will enable the university to obtain an adequate faculty and facilities for teaching, and \$1,600,000 will be given during the first five years for operating and equipment expenses and for development. A \$5,000,000 building to house the school will be erected as soon as the school is accredited and the university is able to integrate its medical schools and hospitals in the medical center. The final \$3,000,000 will be paid within five years, when the school has developed "into a successful undertaking." Dr. Parran is a graduate of Georgetown University School of Medicine, Washington, D. C. He joined the public health service in 1917 and in 1936 began the first of three terms as Surgeon General. From 1930 to 1936 he was commissioner of health for New York State. Since early in 1948 he has served as chief of a mission to the Far East for the United Nations International Childrens Emergency Fund. His most recent assignment was chairman of the U. S. delegation to the first World Health Organization meeting in Geneva, Switzerland, June-July, 1948.

SOUTH DAKOTA

University Appointments.—Recent appointments to the University of South Dakota School of Medical Sciences, Vermillion, include: Dr. Thomas E. Eyres, professor of public health and director of student health; assistant professors, Dr. Jacob B. Belogorsky, pharmacology; Harold M. Carlisle, Ph.D., microbiology; Dr. James Y. Clarke, clinical pathology and parasitology, and Robert H. King, Ph.D., biochemistry; clinical associate professor, Dr. David J. Tschetter, radiology; assistant clinical professors, Drs. Brooks Ranney, obstetrics and gynecology, and Theodore H. Sattler, medicine; research assistant professor of oncology, Dr. Francis C. Tucker; associates, Keatha K. Krueger, Ph.D., biochemistry, and Dr. Theodore T. Mazur, anatomy; Kenneth R. Berquist, M.A., instructor in microbiology. Drs. E. M. Stansbury and Harold F. Hansen were promoted to clinical associate professors of obstetrics and gynecology and physical diagnosis, respectively.

WASHINGTON

Dr. Ripley Appointed Head of the Department of Psychiatry.—Dr. Herbert S. Ripley, assistant professor of psychiatry at Cornell University Medical College, New York, has been appointed professor of psychiatry and executive officer of the department of psychiatry at the University of Washington School of Medicine, Seattle. Dr. Ripley obtained his M.D. degree at Harvard Medical School, Boston, 1933. He has served on the staff of the New York Hospital and has been assistant, instructor and assistant professor in psychiatry, all at Cornell. Following his service during World War II, he served as consultant in psychiatry for the Veterans Administration and since 1947 has been consultant in psychiatry for the U. S. Public Health Service.

WISCONSIN

Personal.—The Biological Photographic Association recently gave its first annual award to Leo C. Massopust, director of the department of art and photography, Marquette University School of Medicine, and editor of the association's journal.

Dedicate Coolidge Laboratory.—Dedication ceremonies for the William D. Coolidge Laboratory of the General Electric X-Ray Corporation, Milwaukee, were held at the laboratory September 13. Among the speakers were Dr. Arthur C. Christie, Washington, D. C., who spoke on "Contributions of Industrial Research to Medicine." William D. Coolidge, Ph.D., who retired in 1944 as vice president and director of research of the General Electric Company, spoke on "Highlights of the Past and a Challenge for the Future." Charles E. Wilson, president, General Electric Company, was speaker at the dinner.

HAWAII

Personal.—Dr. Robert H. Marks, chief of the Tuberculosis Bureau of the Territorial Department of Health, Honolulu, has resigned to return to the mainland as medical director of Jefferson Tuberculosis Sanatorium, Birmingham, Ala.

Health Department Appointments.—Dr. Angie Connor, recently associated with the Children's Heart Association in Cincinnati, began duties July 1 as clinical pediatrician in the Bureau of Maternal and Child Health and Crippled Children. She is a graduate of Woman's Medical College of Pennsylvania, Philadelphia, 1937. Dr. Yan Tim Wong assumed duties July 1 as assistant chief and child psychiatrist with the Bureau of Mental Hygiene. He is a graduate of Peiping Union Medical College, China, where he served as assistant physician in neuro-psychiatry.

PUERTO RICO

Foreign Physicians Wanted.—Governor Jesus T. Piñero of Puerto Rico has signed a bill appropriating the sum of \$80,000 to contract the services of physicians in the United States and foreign countries to be employed in the municipal hospitals of the island where there is a shortage of doctors. Such physicians must sign a contract to serve with the Insular or Municipal governments of Puerto Rico, in accordance with conditions stipulated by the Commissioner of Health. According to Governor Piñero the 1947 mortality rate in Puerto Rico was 12.50 persons per thousand population, compared with 14.1 per cent in 1945. Infant mortality, which was of 39.5 in 1945 per thousand, dropped to 17.5 in 1947. The death rate for tuberculosis which was 202.5 per 100,000 inhabitants in 1945, dropped to 196.7 in 1947. Victims of malaria in 1945 were 43.1 per 100,000 population against 20.0 in 1947.

GENERAL

Society Election.—At the recent meeting of the Harvey Cushing Society Dr. Winchell McK. Craig, Rochester, Minn., was elected president; Dr. Howard A. Brown, San Francisco, vice president, and Dr. Louise C. Eisenhardt, New Haven, Conn., secretary-treasurer.

International College of Surgeons.—The Annual Assembly and Convocation of the United States Chapter, International College of Surgeons, will be held at the Kiel Auditorium, St. Louis, November 16-19. The program of scientific sessions will be supplemented by operative and nonoperative clinics in hospitals in St. Louis and vicinity. Extensive technical and commercial exhibits and motion pictures are scheduled.

Meeting of Public Health Association.—The annual meeting of the American Public Health Association and its twenty-nine related organizations will be held in Mechanics Hall, Boston, November 8-12. More than three hundred papers will be presented before the association's twelve sections: Dental health, engineering, epidemiology, food and nutrition, maternal and child health, health officers, industrial hygiene, laboratory, public health education, public health nursing, school health and vital statistics.

Grant by American Heart Association.—A \$25,000 grant from The American Heart Association has been presented to the Szent Gyorgyi Research Foundation, to aid studies in muscular contraction being conducted at the Marine Biological Institute, Woods Hole, Mass. The grant is the first in a program of financial assistance to heart disease research, which the association has been enabled to undertake as a result of its initial nationwide fund-raising campaign earlier this year. Dr. Szent Gyorgyi is director of research for the foundation, incorporated this year to aid scientific and educational research.

Southern Medical Association.—This association will convene in Miami, Fla., October 25-28 with headquarters at Dinner Key. The program will open with three general sessions which include a panel discussion on anticoagulant therapy and cardiovascular disease with Dr. E. Sterling Nichol, Miami, moderator, and another on peripheral vascular disease with Dr. George D. Lilly, Miami, moderator. The remaining program is divided into numerous sections on the specialties. The president's reception and ball will be held at the Municipal Auditorium in Bayfront Park October 27. The Woman's Auxiliary will meet in conjunction with the association.

Tuberculosis Death Rate Higher for Men.—According to the U. S. Public Health Service, tuberculosis statistics for the past thirty-seven years show that the death rate from tuberculosis in the United States is nearly twice as great for men as for women. During this period the death rate for the disease in the country as a whole has declined from 153.8 to 36.4 per year per 100,000 population. At the beginning of the period the death rate for both white and nonwhite males was about one-fifth higher than the rate for females, but in 1946 there was a

difference of more than 90 per cent between white men and white women. Among the colored population the death rates were 34 per cent higher for males than for females.

Improved Cancer Mortality Among Women.—Decline in the mortality from cancer, including the leukemias and Hodgkin's disease, among women insured in the Industrial Department of the Metropolitan Life Insurance Company has continued almost without interruption from 93.5 per 100,000 in 1932-1934 to 82.9 in 1947. These encouraging trends are attributed to the persistent campaign in popular education regarding cancer, which has resulted in women's seeking medical attention earlier, when the chances of cure are more favorable. Patients who had delayed three months or more decreased from 62.3 per cent of the total from 1923 to 1938 to 42.8 per cent in 1946. In contrast, the recorded death rate from cancer among white females at 1 to 24 years rose from about 5 per 100,000 in 1932-1934 to 6.8 per cent in 1945-1947. The study was published in the *Statistical Bulletin* in August.

Incidence of Poliomyelitis.—The U. S. Public Health Service reported September 22 that 1,841 cases of poliomyelitis were reported for the previous week. In general the incidence declined in the Southern states but increased in the Northern states and in California. Increases aggregating 381 cases were reported as follows: California, 205 to 326; Ohio, 79 to 149; South Dakota, 10 to 55; Illinois, 71 to 99; Tennessee, 13 to 38; Pennsylvania, 51 to 74; New Jersey, 50 to 71; New York, 95 to 115; Minnesota, 101 to 115, and Michigan, 57 to 71. The most important decreases were reported in South Carolina, from 112 to 76; Texas, from 57 to 42; West Virginia, from 28 to 10, and Oklahoma, from 37 to 19. Total cases reported through the week ended September 18 was 16,029, as compared with 5,617 in 1947, 15,780 in 1946, and a five year median of 8,009 for the corresponding periods.

Mental Hygiene Committee.—The annual meeting of the National Committee for Mental Hygiene will be held on November 3-4 at the Hotel Pennsylvania, New York. The program will consist of four scientific sessions during the mornings and afternoons, a business luncheon on the first day and the annual luncheon on the second day, at which the presentation of the Lasker Award will be made and the ten year national program for mental health discussed. The first scientific session will be devoted to international matters emerging from the International Congress on Mental Health held August 11-21 in London, the program of UNESCO and the World Health Organization and the newly organized World Federation for Mental Health. The second session will be a current evaluation of the federal mental hygiene program. The third session will focus on the development and responsibility of the citizen for improvement of the state psychiatric services, and the fourth session will clarify the foundations for positive mental health and the activities supportive of this goal.

Grants for Research.—The Jane Coffin Childs Memorial Fund for Medical Research has announced a total of \$84,275 for support of cancer research projects and fellowships. Among the grants were \$4,100 for one year to Dr. William B. Atkinson, assistant professor of anatomy, and Dr. Howard C. Taylor Jr., professor of obstetrics and gynecology, Columbia University College of Physicians and Surgeons, New York, for cytochemical investigations on hyperplastic and malignant uterine tissues in women in relation to their endocrine state; \$15,000 for three years to Edward L. Tatum, Ph.D., Stanford University School of Medicine, San Francisco, for studies on gene mutation in micro-organisms in relation to enzyme production and activity, and \$5,000 for one year to Dr. Gray H. Twombly, assistant professor of clinical obstetrics and gynecology, Columbia University College of Physicians and Surgeons, New York, for a study of selective localization of hormones in normal and cancer-bearing tissues by radioactive estrogens and allied substances.

New Cancer Journal.—A monthly journal, *Cancer*, devoted exclusively to cancer, with major emphasis on clinical reports and experimental studies, appeared in May of this year. In addition to the original papers, it includes a complete current bibliography of the world-scattered literature on cancer, as well as abstracts of all significant papers. The journal, sponsored by the American Cancer Society, contains no paid advertising, has an attractive format and is liberally illustrated. The editor is Dr. Fred W. Stewart, New York. The editorial advisory board is made up of forty-four leaders in the study and treatment of cancer and seven authorities on education and public health statistics. The first issue was dedicated to the memory of Dr. James Ewing (1866-1943), American pioneer in neoplastic diseases. Subscriptions and business inquiries should be addressed to the American Cancer Society, 49 East 33rd Street, New York 16. Contributions should be addressed to the editor, Memorial Hospital, 44 East 68th Street, New York 21.

Interim Report of the National Foundation.—The National Foundation for Infantile Paralysis in its 88 page interim annual report published early in September showed that a total of \$4,675,971 in March of Dimes funds was allocated to poliomyelitis research, education and epidemic aid during the seven month period ending Dec. 31, 1947. The report announced that \$474,827 was spent on virus research, \$254,480.13 in research on prevention and treatment of after-effects, \$160,000 for medical care, \$1,022,045.96 for professional education and \$2,764,618.30 for emergency epidemic aid. In the past five years 81,530 cases of poliomyelitis have been reported as compared with 31,993 in the previous five year period. Nationally, epidemics of 1947 showed a total of 10,734 cases as compared with 25,698 in 1946. In 1947 three states, Ohio, Idaho and Delaware, suffered their most severe epidemics of poliomyelitis. In professional education the National Foundation has spent \$4,382,994 in the last decade on advanced training for nurses, physical therapists, orthopedists, pediatricians, neurologists and other specialists; a parallel program has been carried on to educate and inform the public.

The World Health Assembly.—Representatives and observers from sixty-eight nations met at Geneva, Switzerland, June 24 to July 24, to form the permanent structure of the World Health Organization. Of fifty health activities considered, priority was given to global campaigns against malaria, tuberculosis, venereal infections and the promotion of maternal and child welfare, better nutrition and environmental hygiene. Work is being continued by the World Health Organization in international epidemiology and quarantine; health statistics and nomenclature; fellowships, medical literature and emergency services. International standards, including therapeutic, prophylactic, diagnostic agents, the international pharmacopeia, editorial services and publications, including reference services and library, were also considered.

Dr. Brock Chisholm of Canada was elected the World Health Organization's first director-general. Prior to becoming executive secretary of the Interim Commission of the World Health Organization in 1946, Dr. Chisholm had served since November 1944 as Canada's first Deputy Minister of Health. The appointed, eighteen member, executive board met under the chairmanship of Sir Aly Tewfik Shousha Pasha, Egypt.

Budgets of \$4,800,000 for the rest of 1948 included repayment of a \$2,000,000 loan from United Nations; \$5,000,000 was approved for 1949. At the invitation of the Pasteur Institute of Paris, the World Health Organization will make use of its many laboratories throughout the world in studying epidemiologic diseases.

CORRECTION

Artificial Kidney.—In the article of this title by Gordon Murray and co-workers in *THE JOURNAL* Aug. 28, 1948, table 2, page 1597, the last chemical mentioned in the formula should be "sodium bicarbonate" and not "sodium carbonate."

Marriages

JACK WHITE McELWAIN, Syracuse, N. Y., to Miss Ruth Van Deventer Jones at Locust Valley, L. I., June 12.

ROBERT BEENE PENDER, Utica, N. Y., to Miss Alice Culpepper Gordon of Daytona Beach, Fla., June 12.

WILLIAM CECIL BAKER, Williamsville, N. Y., to Miss Dorothy Louise Herron of Five Mile, June 19.

JAMES ENGLISH COUSAR III to Miss Mary Evelyn Young, both of Florence, S. C., June 19.

ROBERT WHEARY IRVIN JR., Roanoke, Va., to Miss Dorothy Louise McGee of Ford, June 21.

JAMES EDWARD RYAN to Miss Mary Margaret Douglas, both of Schenectady, N. Y., June 12.

HARRY C. FOSTER JR., Richmond, Va., to Miss Billie Newton of Charlotte, N. C., June 26.

JOSEPH E. MOLLOY, Hilo, Hawaii, to Miss Ruth W. Hopton of Marseilles, Ill., June 9.

JOHN EDWARD DAVIS JR., to Miss Janet Edith Hannon, both of Troy, N. Y., May 15.

WILLIAM FRANK to Miss Betty Rose Smith, both of Washington, D. C., recently.

WILLIAM F. HEGGLI, San Francisco, to Miss Lucille Hottel at St. Louis, recently.

Deaths

John Aikman * Rochester, N. Y.; born in Roxbury, N. Y., Jan. 12, 1885; University and Bellevue Hospital Medical College, New York, 1908; assistant professor of pediatrics at the University of Rochester School of Medicine and Dentistry; specialist certified by the American Board of Pediatrics; member of the American Academy of Pediatrics; past president of the Rochester Academy of Medicine which in 1948 awarded him the Albert David Kaiser Medal for outstanding medical service; chairman of the Section on Pediatrics of the American Medical Association from 1944 to 1946; served during World War I; affiliated with the Strong Memorial, Park Avenue, Genesee and Rochester General hospitals; died July 13, aged 63, of cerebral thrombosis.

Leo Winter, New York; born in New York, May 26, 1890; University and Bellevue Hospital Medical College, New York, 1934; also a dentist; professor of oral surgery and director of the oral and minor surgery clinic, New York University College of Dentistry; member of the American Medical Association; fellow of the American College of Surgeons; served in France during World War I; consulting oral surgeon, Montefiore Hospital for Chronic Diseases; visiting dental surgeon, Bellevue and New York Foundling hospitals; author of "A Textbook of Exodontia" and "Operative Oral Surgery"; an honorary medical officer of the fire department; died in Lawrence, Long Island, July 6, aged 58, of heart disease.

Frank John Novak Jr., * Chicago; born in Chicago, July 3, 1888; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1914; specialist certified by the American Board of Otolaryngology; member of the American Laryngological, Rhinological and Otolological Society and the American Otolological Society; in 1948 received a gold medal from the American Academy of Ophthalmology and Oto-Laryngology for his many years' service to the academy; served during World War I; lieutenant colonel, medical corps, Army of the United States, not on active duty; on the staff of the Henrotin Hospital; died at Riverside, Ill., July 27, aged 60, of coronary sclerosis.

J. Wilford Allen, South Kent, Conn.; New York Homeopathic Medical College and Hospital, New York, 1895; served on the faculty of his alma mater and a member of the Connecticut Homeopathic Medical Examining Board; formerly on the staffs of the Hahnemann and Flower hospitals in New York; died in the Charlotte Hungerford Hospital in Torrington, July 17, aged 83, of fracture of the neck of the femur and arteriosclerotic heart disease.

Edward Lawrence Asbell * Kansas City, Kan.; St. Louis College of Physicians and Surgeons, 1896; affiliated with Providence, Bethany and St. Margaret's hospitals; died July 3, aged 75, of heart disease.

Zae R. AschenBrenner * Farmington, Mich.; State University of Iowa College of Medicine, Iowa City, 1920; past president of the Oakland County Medical Society; served during World War I; for many years president of the school board; died in the Harper Hospital, Detroit, July 20, aged 55, of acute lymphatic leukemia.

Paul Herbert Bishop Jr., Coraopolis, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1943; interned at the Williamsport Hospital in Williamsport; formerly resident at the Veterans Administration Hospital in Memphis, Tenn.; served during World War II; died July 5, aged 30.

Ernest Lehman Wheeler Brown, Iowa Falls, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; member of the American Medical Association; veteran of the Spanish-American War; died July 19, aged 73.

Frederic Bushong * Pottstown, Pa.; Jefferson Medical College of Philadelphia, 1907; died April 15, aged 68, of chronic rheumatic heart disease.

Alexander McConall Butts, Holdenville, Okla.; Vanderbilt University School of Medicine, Nashville, Tenn., 1895; died July 2, aged 77.

James Graham Calhoun, St. Louis; Washington University School of Medicine, St. Louis, 1896; specialist certified by the American Board of Ophthalmology; member of the American Medical Association and American Academy of Ophthalmology and Otolaryngology; served during World War I; died in Deaconess Hospital July 5, aged 79, of subarachnoid hemorrhage and hypertension.

Robert E. L. Campbell * Baltimore; University of Maryland School of Medicine, Baltimore, 1904; also a graduate in pharmacy; died in the Maryland General Hospital June 30, aged 73, of bronchopneumonia and carcinoma of the stomach.

C. Gray Capron * Utica, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1890; surgeon in chief at the Commercial Travelers Mutual Accident Association; died in Cooperstown, July 10, aged 81, of coronary thrombosis.

Clarence A. Carpenter * Onaway, Mich.; Physio-Medical College of Indiana, Indianapolis, 1898; first president of the Presque Isle County Medical Society; formerly health officer of Onaway; died in Little Traverse Hospital, Petoskey, July 17, aged 73, of carcinoma of the stomach with metastases to the liver.

Rodolph Kossuth Comeaux, Youngsville, La.; University of the South Medical Department, Sewanee, Tenn., 1903; died June 12, aged 69.

William Cornelius Couch, St. Petersburg, Fla.; Gross Medical College, Denver, 1895; member of the American Medical Association and the Medical Society of the State of New York; formerly practiced in Watertown, N. Y., where he was on the staffs of the House of the Good Samaritan and Mercy Hospital, where he died July 5, aged 78, of carcinoma of the stomach.

Reuben Cronson * New Rochelle, N. Y.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1888; a founder and past president of the medical board of Jewish Memorial Hospital in New York; died in Miami Beach, Fla., July 4, aged 87, of myocardial failure.

Percy Edwin Decatur, Ashland, Ohio; Eclectic Medical College, Cincinnati, 1904; member of the American Medical Association; served during World War I; member of the staff of Samaritan Hospital; died May 30, aged 73, of injuries received in a fall.

Enos Goble Denison * Sheridan, Wyo.; Ohio Medical University, Columbus, 1903; past president of the Wyoming Department of Public Health; served during World War I; on the staff of Sheridan County Memorial Hospital; division surgeon for the Chicago, Burlington and Quincy Railroad; died May 12, aged 73, of coronary thrombosis.

Clifford Ferrins Dowkontt, New York; Yale University School of Medicine, New Haven, 1919; died July 13, aged 55.

Charles Daniel Eby * Leigh, Neb.; University of Nebraska College of Medicine, Omaha, 1904; died in Lutheran Hospital, Omaha, July 28, aged 69, of cerebral embolism.

Edward Hollinger Epler, Philadelphia; Medico-Chirurgical College of Philadelphia, 1910; died May 6, aged 73, of acute coronary occlusion.

Fred Franklin Farr, Neelsville, Mo.; Barnes Medical College, St. Louis, 1898; died June 28, aged 70.

Charles Wilmer Fitch, New York; Columbia University College of Physicians and Surgeons, New York, 1899; member of the American Medical Association; died July 1, aged 74, of arteriosclerotic heart disease.

Zenobia Gustava Gilpin, Richmond, Va.; Howard University College of Medicine, Washington, D. C., 1923; on the staff of Richmond Community Hospital; served on the city lunacy commission; died June 11, aged 48.

Oswald Glasberg, New York; Medizinische Fakultät der Universität, Wien, Austria, 1926; member of the American Medical Association; died July 15, aged 49.

Onslow Allen Gordon * Brooklyn; Long Island College Hospital, Brooklyn, 1911; formerly clinical professor of obstetrics and gynecology at the New York University College of Medicine; served during World War I; fellow of the American College of Surgeons; fellow and past president of the New York Obstetrical Society and the Brooklyn Gynecological Society; affiliated with the Carson C. Peck Memorial Hospital; consultant in obstetrics at St. John's Hospital; died July 7, aged 61, of carcinomatosis.

Harry Hinshillwood, Danville, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1895; died recently, aged 79, of cerebral thrombosis and hypertension.

Allen Webb Hobby, Sidney, Ohio; Eclectic Medical Institute, Cincinnati, 1899; died recently, aged 71, of cerebral hemorrhage.

Robert Edward Hogan * West Plains, Mo.; Washington University School of Medicine, St. Louis, 1909; member of the school board; president of the West Plains Bank; owner of the Christa Hogan Hospital; died in Missouri Baptist Hospital, St. Louis, July 8, aged 60, of pneumonia, following an operation.

Henry Lincela Houghton, Boston; Harvard Medical School, Boston, 1894; member of the American Medical Association; at one time member of the board of registration in medicine; during World War I head of the medical examining board for the draft in Boston; past president of the Hahnemann Hospital; died June 17, aged 80, of arteriosclerotic heart disease.

Mortimer A. Houser ☉ Tulsa, Okla.; Milwaukee Medical College, 1903; for many years official examiner for the city athletic commission; died in Bentonville, Ark., June 20, aged 70, after an operation.

Charles Bartholomew Howard, Philadelphia; Howard University College of Medicine, Washington, D. C., 1922; died June 7, aged 59, of heart disease.

William L. Howard, Western State Hospital, Tenn.; Memphis (Tenn.) Hospital Medical College, 1895; member of the American Medical Association; specialist certified by the American Board of Otolaryngology; assistant physician at Western State Hospital; died in Campbell's Clinic, Memphis, July 3, aged 76, of embolism, following a fractured hip received in a fall.

John David Howland, Cheektowago, N. Y.; Niagara University Medical Department, Buffalo, 1891; served during the Spanish-American War and in France during World War I; formerly deputy medical examiner for Erie County; for many years associated with the Erie County Home and Infirmary in Buffalo; died in Buffalo General Hospital June 16, aged 83, of carcinoma.

Clarence Elmer Hyde, San Francisco; Columbia University College of Physicians and Surgeons, New York, 1909; member of the American Medical Association; died in San Jose, June 6, aged 66, of bronchopneumonia and arteriosclerosis.

Lucia Kemp, Bucyrus, Ohio; Fort Wayne College of Medicine, 1891; died June 24, aged 85.

Lester Floyd Kennedy ☉ Detroit; Detroit College of Medicine and Surgery, 1915; died June 28, aged 56.

Ralph William Kraft ☉ Hobart, Ind.; Indiana University School of Medicine, Indianapolis, 1936; at one time assistant superintendent of the Ohio State Sanatorium in Mount Vernon; member of the staffs of Mercy and Methodist hospitals in Gary and Porter Memorial Hospital in Valparaiso; served as health commissioner and school physician; accidentally shot and killed in a hunting lodge near Ely, Minn., June 23, aged 38.

Harry Lee, Waterhill, Tenn.; University of Tennessee Medical Department, Nashville, 1900; died May 20, aged 73, of nephritis and myocardial insufficiency.

Joseph Ira Lindsay, Grafton, Mass.; University of Vermont College of Medicine, Burlington, 1888; member of the American Medical Association; formerly on the staff of Memorial Hospital, Worcester; died June 6, aged 85.

Herbert Milton Long ☉ Pittsburgh; University of Pittsburgh School of Medicine, 1914; fellow of the American College of Surgeons; chief surgeon for the Pittsburgh and Lake Erie Railroad; served during World War I; member of the staff of the Southside Hospital; died June 15, aged 58, of sarcoma.

Frederick Henry Lovell, Irvington, N. J.; the Hahnemann Medical College and Hospital, Chicago, 1909; served on the staff of the Irvington General Hospital, where he died July 6, aged 87, of arteriosclerosis.

James Chalmers Lyons, Linwood, Pa.; Jefferson Medical College of Philadelphia, 1909; died June 15, aged 67, of coronary occlusion.

Elmer Ellsworth Mace ☉ New Palestine, Ind.; Medical College of Indiana, Indianapolis, 1902; served during World War I; died in St. Vincent's Hospital, Indianapolis, July 1, aged 71, of coronary occlusion.

Donald MacIntyre, Big Rapids, Mich.; Michigan College of Medicine and Surgery, Detroit, 1897; member of the American Medical Association; for many years county coroner; past president and secretary of the Mecosta County Medical Society; on the staff of Community Hospital; died June 30, aged 75, of arteriosclerosis.

Robert Donald MacKinnon ☉ Philadelphia; Temple University School of Medicine, Philadelphia, 1913; instructor in surgery at his alma mater; served in the Boer War and with the Canadian Army Medical Corps during World War I; affiliated with the Temple University Hospital, where he died June 11, aged 70 of arteriosclerosis and abdominal aortic aneurysm.

Marcus J. Magruder, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1889; past president, Orleans Parish Medical Society; and vice president of the Louisiana State Medical Society; affiliated with the

Touro Infirmary; in 1946 resigned from the board of administrators of the Tulane Education Fund; received the honorary degree of doctor of laws from Tulane in 1946; died July 4, aged 82, of arteriosclerosis.

Joseph Crockett Manning, Savannah, Mo.; University Medical College of Kansas City, 1913; president of the school board; affiliated with St. Francis Hospital, Maryville, St. Joseph's Hospital and the Missouri Methodist Hospital, where he died June 10, aged 61, of cerebral hemorrhage.

Charles Beverly Martin, Bowling Green, Ky.; University of Louisville (Ky.) Medical Department, 1890; shot to death June 30, aged 83.

Clarence Randle McDonald, Mannford, Okla.; University of Tennessee Medical Department, Nashville, 1909; past president of the Creek County Medical Society; served during World War I; died in the Hillcrest Hospital, Tulsa, June 5, aged 65, of coronary thrombosis.

Neill Smith McLeod, Highland Park, N. J.; Johns Hopkins University School of Medicine, Baltimore, 1924; member of the American Medical Association; died June 7, aged 50.

Thomas Reid McNab, Beverly Hills, Calif.; Medical Department of the University of California, San Francisco, 1903; served during World War I; formerly on the faculty of his alma mater; member of the founders group of the American Board of Surgery; member of the Pacific Coast Surgical Association; fellow of the American College of Surgeons; served on the staff of the Hospital of the Good Samaritan in Los Angeles; died in Honolulu, Hawaii, June 21, aged 70, of acute coronary thrombosis.

James Mansfield Meason, Chandler, Ariz.; Maryland Medical College, Baltimore, 1905; at one time in the Indian Service; formerly mayor of Chandler; county health officer; died in the Good Samaritan Hospital, Phoenix, June 22, aged 70.

Ray Sixtus Nelson ☉ New York; Syracuse University College of Medicine, 1911; formerly on the faculty of the New York Post-Graduate Medical School and Hospital, Columbia University, New York; served during World War I; on the staffs of Gotham and St. Francis hospitals; died June 18, aged 63, of coronary thrombosis.

William Clark Newcome, Indiana, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1892; member of the American Medical Association; a member of the staff of Adrian Hospital in Punxsutawney; died in Miami, Fla., May 30, aged 80, of cerebral hemorrhage.

Z. Oliver Nobert, Rome, N. Y.; Bennett Medical College, Chicago, 1891; died June 27, aged 86, of carcinoma of the pharynx and coronary sclerosis.

Anthony E. Otto, Alexandria, Ind.; Medical College of Ohio, Cincinnati, 1883; member of the American Medical Association; died June 3, aged 86, of cardiovascular-renal disease.

Wilfred Rossner Parsons, Little Rock, Ark.; University of Arkansas School of Medicine, Little Rock, 1932; member of the American Medical Association; assistant professor of pediatrics at his alma mater; served during World War II; affiliated with St. Vincent Infirmary, Baptist State Hospital, Arkansas Children's Home and Hospital and University Hospital; died June 13, aged 43, of coronary occlusion.

Marion Lee Peeples, Scotia, S. C.; University of Louisville (Ky.) Medical Department, 1891; member of the American Medical Association; died June 16, aged 77.

Wallace Bernard Pyle ☉ Jersey City, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; member of the staffs of the Bayonne (N. J.) Hospital and Dispensary, St. Francis Hospital, Jersey City Medical Center and Christ Hospital; one of the founders and a trustee of Fairmount Hospital; died in Orange June 10, aged 71, of cerebral hemorrhage.

Rufus Livius Raiford ☉ Franklin, Va.; University College of Medicine, Richmond, 1906; founder and until recently chairman of the board of Raiford Memorial Hospital; for many years secretary of the Southside Medical Association; died June 25, aged 67, of coronary thrombosis.

Carl Frost Raver, Charleston, W. Va.; University of Michigan Homeopathic Medical School, Ann Arbor, 1901; served as health officer of Mankato, Minn., Aberdeen, S. D., and La Salle, Ill.; formerly director of the division of vital statistics, state board of health; died June 11, aged 69, of carcinoma of the larynx.

Simon Warren Reichard, Dayton, Ohio; Medico-Chirurgical College of Philadelphia, 1901; member of the American Medical Association; served during World War I; on the staffs of Good Samaritan and St. Elizabeth's hospitals; affiliated with the Veteran Administration Hospital where he died June 19, aged 70, of cerebral hemorrhage and hypertension.

Anna Magilowa Reinstein, Cheektowaga, N. Y.; Universität Bern Medizinische Fakultät, Switzerland, 1891; died June 21, aged 82, of diabetes mellitus and gangrene of the foot.

Joseph Anthony Rucker, Bedford, Va.; University of Louisville (Ky.) Medical Department, 1893; member of the American Medical Association; past president of the Bedford County Medical Society; for many years secretary of the county board of health; in 1947 was awarded the diamond insignia, symbol of fifty or more years of service with the Norfolk and Western Railway; died June 29, aged 77, of cerebral hemorrhage.

Ralph M. Ryan, Antonito, Colo.; Bennett Medical College, Chicago, 1912; member of the American Medical Association; served during World War I; died in St. Joseph's Hospital, Del Norte, June 30, aged 75, of heart disease.

Edward Saylor, Phillipsburg, Mo.; Missouri Medical College, St. Louis, 1884; member of the American Medical Association; died in St. John's Hospital, Springfield, June 23, aged 93, of fracture of the neck of the right femur and prostatic hypertrophy.

Joseph Scattergood Jr., West Chester, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1929; member of the House of Delegates of the American Medical Association from 1942 to 1944; secretary treasurer of the Chester County Medical Society; medical director of Darlington Sanatorium and Chester County Hospital, where he died June 4, aged 43, of uremia.

Howard Francis Schell, Cincinnati; University of Michigan Homeopathic Medical School, Ann Arbor, 1904; died in the Christ Hospital June 16, aged 68, of uremia and prostatic hypertrophy.

Bernard Schwartz, Philadelphia; Jefferson Medical College of Philadelphia, 1908; member of the American Medical Association; served on the staff of Northern Liberties Hospital, where he died June 25, aged 71, of pulmonary hemorrhage.

Alfred N. Shotwell, Mount Clemens, Mich.; Detroit Medical College, 1884; died in June, aged 90, of cerebral hemorrhage.

John A. Shower, York, Pa.; Southern Homeopathic Medical College, Baltimore, 1894; member of the American Medical Association; died June 24, aged 88, of carcinoma of the descending colon.

Albert Ernest Small Ⓢ Melrose, Mass.; Harvard Medical School, Boston, 1900; served during World War I; on the staff of Melrose Hospital; chairman of the board of health; died in Palmer Memorial Hospital, Boston, June 9, aged 72, of recurrent carcinoma of the rectum.

Marianna Eddy Smalley Ⓢ Ann Arbor, Mich.; University of Michigan Medical School, Ann Arbor, 1931; instructor in internal medicine at her alma mater; member of the American Trudeau Society, American Association of the History of Medicine and the Michigan Trudeau Society; on the staff of St. Joseph's Hospital; died June 21, aged 44.

Francis Henney Smith Ⓢ Abingdon, Va.; University College of Medicine, Richmond, 1904; specialist certified by the American Board of Internal Medicine; past president of the Southwestern Virginia Medical Society and the Medical Society of Virginia; served during World War I; a member of the state board of medical examiners; fellow of the American College of Physicians; affiliated with the George Ben Johnston Memorial Hospital; died July 1, aged 67.

Horace R. Stauffer, Nappanee, Ind.; Rush Medical College, Chicago, 1883; for many years member of the state legislature; died July 2, aged 90.

Dudley Donnelly Stetson Ⓢ Santa Fe, N. M.; Colorado School of Medicine, Boulder, 1905; specialist certified by the American Board of Dermatology and Syphilology; formerly on the faculty of the New York Post-Graduate Medical School and Hospital, Columbia University; at one time on the staffs of Lincoln and Roosevelt hospitals in New York; died June 14, aged 70, of heart disease.

John Coleman Stiles, Dallas, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1898; member of the American Medical Association; died in the Methodist Hospital May 11, aged 74, of cerebral hemorrhage and pyelonephritis.

Charles Frederick Stotz Ⓢ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; fellow of the American College of Surgeons; a trustee of the Chicago Medical Society; a member of the "Fifty Year Club" of the Illinois State Medical Society; connected with Walther Memorial Hospital since its founding, serving as chief of staff, president of staff and president emeritus; died July 18, aged 75, of carcinoma.

Frank Raphael Strong, Brewerton, N. Y.; Syracuse University College of Medicine, 1904; died in the University Hospital, Syracuse, June 20, aged 72, of a hip fracture received in a fall and arteriosclerotic heart disease.

William Herman Sugarman Ⓢ Brooklyn; Cornell University Medical College, New York, 1914; specialist certified by the American Board of Internal Medicine; affiliated with the Brooklyn Hebrew Home and Hospital for Aged and the Jewish Hospital, where he died June 23, aged 59, of acute coronary occlusion with myocardial infarction.

Frank Augustus St. Sure, Haiku, Hawaii; College of Physicians and Surgeons of San Francisco, 1900; veteran of the Spanish-American War; member of the American Medical Association; died June 22, aged 74.

Carol Lincoln Sweet, Los Gatos, Calif.; University of the City of New York Medical Department, New York, 1882; formerly president of the Idaho State Medical Association and secretary of the Idaho State Board of Medical Examiners; veteran of the Spanish-American War and surgeon general of the Idaho National Guard; died June 19, aged 88, of senility.

Franz J. Swoboda, Omaha; University of Nebraska College of Medicine, Omaha, 1905; died June 18, aged 68, of cerebral thrombosis.

Samuel L. Thorpe Ⓢ Major, U. S. Army, retired, Seattle; Northwestern University Medical School, Chicago, 1893; entered the medical corps of the U. S. Army as a captain in 1920; retired Sept. 30, 1933 for disability in line of duty; served during World War I; died in Madigan General Hospital, June 4, aged 78.

William A. Tisdale, Seminary, Miss.; Medical Department of Tulane University of Louisiana, New Orleans, 1890; died in the Methodist Hospital, Hattiesburg, June 7, aged 85.

George Henry Torney Ⓢ Brookline, Mass.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; member of the American Psychiatric Association and the New England Society of Psychiatry; medical director, superintendent and owner of the Bournewood Hospital; died June 1, aged 75, of dissecting aneurysm of the aorta.

Camillo Eugene Volini Ⓢ Chicago; Loyola University School of Medicine, Chicago, 1933; served as president of the Chicago Tuberculosis Society; resigned in January 1948 as superintendent of clinics for the Municipal Tuberculosis Sanatorium, where he had been on the staff for many years; died in Columbus Hospital June 22, aged 40.

Joseph Francis Walsh Ⓢ Eureka, Calif.; Cooper Medical College, San Francisco; 1909; died May 28, aged 63, of heart disease.

Max Wershow, Los Angeles; University of Michigan Medical School, Ann Arbor, 1920; died June 17, aged 60.

Euclid Clarence Wills, Phoenix, Ariz.; Medical College of Virginia, Richmond, 1906; died June 6, aged 63, of coronary disease.

Chester Anderson Witmer Ⓢ Waycross, Ga.; University of Virginia Department of Medicine, Charlottesville, 1911; served in the medical corps of the U. S. Army during World War I; past president of the Ware County Medical Society and the Eighth District Medical Society; city physician; fellow of the American College of Surgeons; chief of staff, Ware County Hospital; local surgeon for the Atlantic Coast Line Railroad; died May 7, aged 60, of mesenteric thrombosis.

Jesse Charles Woodward Ⓢ Payette, Idaho; Gross Medical College, Denver, 1900; died June 23, aged 75, of coronary occlusion.

DIED WHILE IN MILITARY SERVICE

Robert Oscar May, Pittsburgh; Temple University School of Medicine, Philadelphia, 1945; interned at St. Francis Hospital; began active duty as a lieutenant (jg) in the medical corps of the Naval Reserve in April 1946; died in Italy Sept. 26, 1947, aged 27, of injuries received in an automobile accident.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 4, 1948.

Private Practice and the National Health Service

The National Health Service is designed to make the practice of medicine entirely socialistic; however, it has come into force with remarkably little friction. Some trouble has arisen in connection with what are called "health centers." These promise to be a useful innovation by providing buildings where physicians can cooperate and where their time will be saved by a clerical staff undertaking routine duties. The Minister of Health has refused the request of physicians that they should be allowed to treat their private patients at these centers. The general purposes committee of the Birmingham National Health Executive Council is so seriously concerned with this refusal that it proposes to take energetic measures to get the ruling reversed at the first annual meeting of the Executive Councils' Association in London. The objection is made that if the Minister's decision is adhered to it may be impracticable to operate health centers. If physicians are not allowed to treat private patients at health centers they will be forced to maintain at extra expense separate offices and to attend at them. Different offices for private and public patients might cause public patients to regard health centers as charitable institutions. Some physicians have intimated that if the Minister's decision is adhered to most general practitioners will not participate in the health center schemes. This refusal of the Minister is only one symptom of the socialistic Government's antagonism to private practice. There seems little doubt that they would have liked to abolish it and convert the doctors into civil servants. Only the stand made by the profession against payment by salary compelled the Government to accept payment by capitation. It was realized by the profession that payment by salary would only be a step to the reduction of physicians to officials entirely controlled by the state. But this remains a danger of the future, which will probably materialize if socialism remains dominant.

The Government's antagonism to private practice is illustrated by another incident. Those who prefer to remain private patients of physicians can continue to do so, but they will be taxed for the National Health Service exactly as those who use it. The modest request was made on their behalf that, as they had foregone the free doctoring, they might be allowed to obtain the free medicine given to those who use the Service, but the Minister has again refused.

Cost of Dentistry Under the National Health Service

The dentists have more strongly opposed the scheme of the National Health Service than the physicians. In a press interview Mr. Buchanan, secretary of the British Dental Association, states that 30,000 estimates for dental work are being received every day by the Dental Estimates Board and that the average cost is more than \$20. This means that the scheme is now costing more than \$600,000 a day, while the Government estimate for a full year is only \$28,000,000. This means that the scheme is costing more than seven times the Government estimate. Many dentists have a large income, but the present scheme must break down sooner or later, and the Ministry of Health will be driven to a reconsideration of the whole matter. The secretary claims that this result shows the wisdom of the policy of grant-in-aid advocated by the association but rejected by the Ministry of Health. The association is also demanding full clinical freedom and a guarantee that the Minister will not introduce a full time dental service by regulation. At a meeting of the Council of the Association it has been decided to send

a further letter to every member advising him not to enter the National Health Service.

This staggering increase of cost of the dental service is, of course, due to the offer of "something for nothing" which characterizes socialistic schemes. Every one who can possibly do so wants to share in the spoils. It might be rejoined that the service is really not free, as the beneficiaries pay by their weekly contributions, but their payments amount to only part of the cost, the rest being made up by the state. In any case the motive to share in the distribution remains exactly as if no contributions were made. This increased cost holds for all the industries that have been socialized. The cost of coal is more than doubled, and notwithstanding this, a loss has been made in the working of the industry. In state-owned industries no one has any interest in economy or efficiency. Late in the day some of the more intelligent members of the Labor Government have grasped the elementary economic truth that a good output is essential for the prosperity of the country and have appealed to the workers to give this. But the politicians have had to admit that the response was "disappointing." Why should it be otherwise when the men are in no danger of dismissal, as in the case of private enterprise. Altruism is no part of the trade union propaganda on which they are fed.

Returning to the dentists, the Ministry of Health says that 7,000 have joined the service, but the association states that almost the whole of this number can be accounted for by dentists who are not members of the association.

Research on the Antigens of Koch's Bacillus

Miss Choucroun has made a communication to the National Academy of Medicine on two isolated fractions of Koch's bacillus, one being protein and the other lipopolysaccharide. She obtained them from an oily extract of dead tubercle bacilli precipitated by the addition of dioxane. The mixture of those two substances dissolves in chloroform to which is added 5 per cent methanol, and their separation is effected by petroleum ether. The author has noted that the lipopolysaccharide fraction plays an important part in the development of hypersensitivity to tuberculin. The purified protein fraction injected into guinea pigs has no sensitizing power, but 20 micrograms of lipopolysaccharide added to 100 micrograms of the proteinic substance is sufficient to give it a sensitizing capacity. Boissevain and Schaffer have brought to light the relation between the acid resistance of Koch's bacillus and its sensitizing capacity; rendered non-acid-resisting by acid hydrolysis, it loses at the same time its sensitizing power. Miss Choucroun has proved that the liposaccharide is the factor responsible for this acid resistance. She found in the products of hydrolysis of acid-resisting bacilli the products of hydrolysis of lipopolysaccharide, mycolic acid and sugars, and, moreover, she has been able to give non-acid-resisting "skeletons" capacity of acid resistance by adding to them the whole lipopolysaccharide, or the mycolic acid and its sugar. The lipopolysaccharide fraction is also the only antigenic complex; i. e., the only one capable of determining the formation of polysaccharide antibodies. The author suggests that those polysaccharide antibodies play an important part in the mechanism of acquired resistance.

Treatment of Eczema

The first works on the treatment of infantile eczema by unsaturated fatty acids (reported to the Medical Society of the Paris Hospitals) have just been published in France. E. Azerad and Crupier have treated 30 children with satisfactory results. They emphasize the remarkable eutrophic effect of this diet. The percentage of linoleic acid in lard varying according to

various factors, the authors have chosen to substitute for lard purified preparations of linoleic acid, or even of an ester of this acid easier to administer and the action of which appears more rapid. J. Charpy (Dijon) has presented his results of three years of experiments in 1,200 cases. The author obtained conclusive results in 80 per cent of cases of various forms of this disease. He gives doses of 20 to 100 Gm. of lard per day according to age and weight. The simultaneous administration of certain elements of the B complex, especially vitamin B₆ in the dose of 0.10 to 1 or 2 Gm. per day has a synergic effect, permitting at the same time the reduction of the dose of unsaturated fatty acids. For the treatment of certain true or allergic eczemas in the infant, the author studied replacing vitamin B₆ with vitamin B₃. J. Champougny and E. Le Breton have recently proved that vitamins B₆, B₃ and B₅ are coenzymes of the "desaturase" of superior fatty acids, but this process occurs only after a previous phosphorylation. The author is studying the way of insuring the maximum of this phosphorylation in the organism, through which he expects an increase of the therapeutic effect. With unsaturated fatty acids and vitamin B₆ the author associated oral intestinal vaccines which seem to increase the effectiveness of the two essential elements of this therapy. He limits the local treatment to dressing with lard or with a mixture of vitamin B₆, wool fat and lard. He insists on the necessity of eliminating allergens, which may, by external contact or by internal route, produce the cutaneous imbalance.

New Treatment of Arteritis of the Limbs

With a view to measuring the blood circulation of limbs in arteritis, Lemaire, Loeper and Housset injected oxygen into the arterial trunk; they noted improvement in most of the patients. They have just reported to the National Academy of Medicine their study of 15 patients: 5 with diabetic arteritis, 7 with senile arteritis, 2 with specific arteritis and 1 with acute arteritis. The injections were made in the femoral artery at the crural arcade. They at first used gaseous oxygen in a volume of 70 to 200 cc. injected in one to two minutes. Recently, in order to facilitate the injection, the authors used 2 cc. of hydrogen peroxide at 30 volumes mixed with 3 cc. of isotonic sodium chloride solution, which yields roughly 90 cc. gaseous oxygen. The results of this treatment, lasting from one to three weeks, are striking: disappearance of the pain and cramp in the calves when walking and in the decubitus position. The effectiveness of this therapy is much more lasting than that of the classic vasodilators. During the injection, the patient experiences sensations of tingling and of burning in the foot and calf, followed either by pallor of the limb or by disks of erythrosis on the leg, scrotum and even the abdomen; the same phenomena, but less accentuated, occur sometimes on the limb which has not received an injection. A few hours afterward the patient has a sensation of heat which persists. Immediately after the injection or later the oscillometric index is not modified; the cutaneous temperature falls for fifteen to thirty minutes and then rises again, and surpasses the previous rate by 2 to 3 C. Failures are rare. Reactions, varying from one patient to another, may occur in the form of lumbago, imperative desire to urinate, violent colic with emission of several stools, slight shivering, temperature of 38 C. (100.4 F.) and slight but temporary fall of the arterial pressure. Only one fatal accident has occurred, in a 55 year old diabetic patient with arteritis of the superior and inferior limbs, who after an efficacious injection, without incident, in the leg was while seated given another one in the subclavian artery. A few seconds, after the beginning of the injection a tonic crisis occurred, then a hemiplegic coma and death a few hours afterward. The authors emphasize that such accidents would never occur if the precaution is taken to put the patient in the Trendelenburg position. Provoked gaseous

emboli in the arteries of the limbs are without any danger whatever, oxygen combining rapidly with hemoglobin. The authors think that the therapeutic effect of this method is due either to compensation for the loss of oxygen due to the slowing of circulation in the arterioles or to reactivation of cellular cytochromes. Moreover, they say such gaseous emboli provoke an arteriolo-capillary vasodilation.

OSLO

(From Our Regular Correspondent)

Sept. 8, 1948.

Don't Just Listen! Take Notes!

Early every September, Oslo suddenly turns academic and university conscious. Everywhere one sees students' caps, with their heavy black silk tassels, crowning thousands of heads, some gray or bald. This emblem of the freemasonry among the intellectuals from all parts of Norway culminates in the University Hall, where this year, on September 2, Professor Otto Lous Mohr, rector of the university, delivered an address. He pointed out that in the early days of the university 60 per cent of the entrants came from the professional classes. Now only 14 per cent do so. Now an academic career is open to all with brains, and 9 per cent come from the homes of farmers and fishermen. Every fifth student is now a woman. Professor Mohr referred with grateful appreciation to the help given to the university by various American organizations, including the Rockefeller Foundation, which has provided not only fellowships and travel grants, but also funds for the purchase of scientific publications. Professor Mohr awarded the much coveted prizes of the year, including the Monrad-Krohn prize for neurologic research, won this year by Dr. Sigvald Refsum for his work on heredopathia atactica polyneuritiformis.

In his first lecture of the autumn term, on Saturday, Sept. 4, Professor Olav Hanssen welcomed the occupants of crowded benches to the study of medicine. Then he sparkled for a solid hour. Behind the sparkle and the whimsical anecdotes was much shrewd advice such as: "Don't just sit there and listen! Take notes all the time!" Then he demonstrated a patient who had been knocked down by a cyclist and had obscure signs and symptoms referred to one leg. Examined successively by a physician, a surgeon and a psychiatrist, he had been suspected of a compensation-hungry neurosis. What a pity that neither the physician nor the surgeon nor the psychiatrist had consented to the roentgenologic examination for which the patient had pleaded! For when at last a roentgenogram was taken, it showed a fracture of the fibula. If only we could learn to take notes of all we hear and see, and take roentgenograms whenever we are in doubt!

Professor Kristine Bonnevie

Miss Kristine Bonnevie, the first woman to gain the title of professor at the University of Oslo, has just passed away, much loved and greatly honored. She was born in Oslo in 1872, and it was here that she passed most of her life, although she was of international stature and had worked in Germany, Switzerland and the United States. She took her degree of Doctor of Philosophy in 1906 and was appointed professor of zoology in 1912. Her scientific interests covered a wide field, and she made important contributions to embryology and the problems of heredity. As recently as last summer, at the age of 76, she took part in the International Congress on Heredity in Stockholm, then as always rubbing shoulders with fellow scientists from all over the world with that unassuming ease which made her such an attractive fellow traveler in life.

To the younger generation and in wide circles, Professor Bonnevie was the beloved "Tante Kristine" to whom one came with one's troubles, whether they were personal or scientific.

Though she never married, she was the most motherly of souls, always on the lookout for an opportunity to give a helping hand when one was in difficulties. During World War I she organized in a cellar in one of the university buildings a kitchen restaurant in which students were provided with meals at cost price. During World War II, though no longer holding the chair of zoology, she again fed young students with unobtrusive efficiency. They showed their appreciation by electing her to places of honor in their various associations, and she was for some years the chairman of the women students' choir. But she was, perhaps, at her best when at work at the biologic station in the Oslo fjord, clad as a seaman, sou'wester and all, reveling in the riches dredged up from the bottom of the sea, and sharing them with her students with open-handed generosity.

Sven Oftedal

He was still rather young when he died, but his career was so brilliant and his personality so charming and forceful that he has left an indelible impression. He was born in Stavanger in 1905 into a family already noted for intellectual gifts. After qualifying as a doctor in 1930 he served as an intern successively in a general hospital, a private asylum and a Red Cross sanatorium. Then, in 1933, he settled down in his native town as a general practitioner. His success in this field did not prevent his taking an active interest in local government, and from 1933 onward he took a prominent part in social work in Stavanger. When the Germans invaded Norway, his glowing patriotism qualified him for arrest as a hostage for his town. A little later the Germans removed this troublesome patriot to the concentration camp at Grini, where, as everywhere else, he soon became a leader of his fellow beings. A pestilential fellow from the German point of view, he had yet to be employed in key positions at Grini. Set free after some time on probation, he became such a nuisance and even danger to the Germans that he had to be arrested again, and, after they had tried to keep him quiet in various prisons in Norway, they sent him in 1943 to the notorious concentration camp of Sachsenhausen in Germany. Here he remained until the end of the war, always the acknowledged leader of his fellow sufferers. On Oftedal's return to Norway in 1945, his appointment to high office was a foregone conclusion. As a member of the Government and head of the Department for Social Affairs, he took an active part during the next three years in the social legislation which has had such far reaching effects in the postwar period. He was still in office and had been on sick leave for only a few weeks when an infarct of the heart ended his career.

SPAIN

(From Our Regular Correspondent) Aug. 12, 1948.

National Institute of Medical Science

The National Institute of Medical Science was founded as a dependency of the Higher Council for Scientific Research by Decree of Dec. 16, 1942, with the object of coordinating the work of all state research centers and more especially of the faculties of medicine in Spanish universities. During its five years of existence and development, the number of its departments has progressively increased, as well as the amount of work done. Twenty-one departments are functioning at present, dealing with the following disciplines and specialties: morphology, human and comparative physiology, immunology and microbiology, experimental pharmacology, metabolic pathology, digestive pathology, internal medicine, experimental surgery, legal medicine and toxicology, medical biochemistry and history of medicine. As a general rule, these departments are linked up with the university departments or with other recognized teaching centers outside the university, such as the Postgraduate Institute at Valdecilla (Santander) and the Basurto Hospital at Bilbao. The institute publishes a quarterly volume comprising

papers on research and called *Trabajos del Instituto de Ciencias Medicas*, of which ten or eleven issues have already appeared, full of important original papers.

The institute looks after the training and guidance of young medical research workers and sends many of them to research centers abroad to acquire knowledge and practice of basic techniques and principles on which to found their future work in Spain. In this respect, the institute fills the place of the old Studies Extension Board.

The head of the institute is the dean of the Madrid Faculty of Medicine, Professor F. Enriquez de Salamanca, who has been doing research since 1925 on the examination and physiology of the human stomach on the same lines as the work started by Lewin and the Katsch school somewhat later, in 1927.

He has been able to determine the volume of secretion and has succeeded in measuring for the first time the rate of secretion in the course of digestion. He has ascertained the variability of the concentration of gastric juice, which may go from 0.5 Gm. per thousand of chloride to more than 6 Gm. per thousand. He has observed a parallelism between the rate of secretion and chloride concentration, but as between different days in the same subject and as between various subjects compared with one another, he found that the quantity of juice was in inverse ratio to the concentration and, in all of them, at the end of digestion there was an even more abundant secretion, though this was poor in chloride and acid.

GERMANY

(From Our Regular Correspondent)

Aug. 31, 1948.

Postwar Goiter in Germany

After the first world war, German physicians described an increased incidence of goiter, even in parts of the country normally free from goiter, like Nuremberg, the Ruhr district and the Northern German plain. In 1924, there was still a high percentage of patients with goiter among adolescents. It decreased markedly toward the end of the twenties.

The same trend has been noted during and after the second world war. This time, however, the situation is complicated by the influx of evacuees and refugees into these districts from parts of former Germany where goiter has always been endemic, and also by the fact that a large proportion of German youths were evacuated from cities and sent to different parts of the country during the war, some of which are also goiter districts. However, various authors writing on the subject have stressed that the appearance of endemic goiter is by no means restricted to such cases. Comparisons of groups of children of early school age showed a moderate increase of the size of the thyroid gland in less than 1 per cent in the late twenties, against more than 20 per cent recently. The same case rate is found in children 11 to 12 years of age. If old and new residents of Central Germany are counted separately, the figures show that among the static group about one fifth and among the refugee group about one third of the children have enlarged thyroid glands.

The cause of this situation is not well understood. There seems to be a lower incidence of goiter in the socially higher strata; therefore, lack of proteins has been considered to be an etiologic factor. Treatment with iodine is of doubtful value. It has been said that these postwar goiters in adolescents are often connected with a delayed sexual development. This would point to an advisability of polyhormonal treatment.

Infantile Paralysis in Bavaria

A serious outbreak of poliomyelitis has occurred in all of Bavaria, particularly in the towns of Hof, Regensburg and Straubing. Health authorities caution that the peak may not be reached before the end of this month. Within one week, the number of affected persons rose from 250 to 410. Eighteen deaths were reported.

Correspondence

MEDICAL EDUCATION IN CHILE

To the Editor:—During the month of July of this year I had the opportunity of visiting most of the important hospitals and medical institutions in Santiago de Chile. It was possible during this time to analyze the organization of their medical services. I was greatly impressed with the very high plane of teaching of medicine in the University of Chile.

Internal medicine is taught on four major services, each headed by a professor of medicine. Two of these services are in the Hospital del Salvador. I particularly wish to comment on the high character of medical teaching on the services of Drs. Hernan Allesandri and Armas Cruz of that hospital because I had the opportunity of observing the work on these two services closely. I have no reason to feel that the medical services of Dr. Garreton at the Hospital San Borja and of Dr. Prado Tagle at the Hospital San Vicente are in any way inferior to the services at the Hospital del Salvador, with which I am more familiar.

On both these services at the Hospital del Salvador, Drs. Allesandri and Armas Cruz have associated themselves with a group of young physicians well trained in the specialties of internal medicine. Many of these young men have been trained in the United States. On these two services, gastroenterology, in which I was particularly interested, was integrated into the medical services and supervised by several well trained young gastroenterologic internists. These two departments of gastroenterology were as well organized as any that I have seen in this country. All the teaching devices utilized in gastroenterology were on hand, and they were applied by well trained men. I was impressed by the close integration of all divisions in medicine under the leadership of these two excellent physicians. Research projects were actively going on in many of the subdivisions of medicine, and the close integration of the various specialties afforded an ideal setup for the carrying out of important clinical research projects.

The criticism often made of Latin American medicine concerning the continuation of older European methods of practice and teaching certainly does not apply to the teaching of internal medicine in the University of Chile in Santiago. The chiefs of the medical services are well versed in modern American medicine, and in some respects their organization is better than that on some of our medical services in this country. For example, all deceased patients are subjected to autopsy by a well trained pathologist assigned to each of these medical services. Each week the students working on both services have the opportunity of attending a medical pathologic conference in which all cases are completely reviewed and discussed. The clinical, roentgenologic and laboratory features of each case are presented and discussed before the necropsy findings are given. Because of the universal autopsy system and the full time services of a pathologist on each medical service, this material can be ideally integrated and important clinical pathologic studies in many diseases are made possible. For example, the analysis of a tremendous number of cases of hepatic cirrhosis, which is common in Chile, is now being prepared on the service of Dr. Armas Cruz and important papers dealing with a large experience with infectious hepatitis are being prepared by Drs. Allesandri and Ducci.

Finally, I should like to comment on the fine scientific spirit and on the medical camaraderie, which are so obvious to the visitor in Santiago. These Chileños are practicing *factual* medicine on a high plane, and a closer association with our colleagues in Chile is highly desirable. Important contributions in medicine may be anticipated from this newly developed medical center.

Before closing I should like to pay my respects to Dr. Gandi, the representative of the Institute of Inter-American Affairs in Chile. This gentleman, ideally suited by personality and training to the position which he holds, has contributed greatly to the healthy spirit of collaboration between the medical scientists of Chile and those of the United States.

H. L. BOCKUS, M.D., Philadelphia.

EFFECT OF PROCAINE ON THE HEART

To the Editor:—The hazards attending the intravenous administration of procaine, recently advocated in the treatment of bronchial asthma and other conditions, have been pointed out by Waldbott in *THE JOURNAL*, April 26, 1947, and again in *Queries and Minor Notes* in the Aug. 21, 1948 issue.

The hazards of this procedure are further indicated by our recent experimental electrocardiographic observations in the dog (*Am. Heart Journal*, in press). These studies revealed that intravenously administered procaine is capable of exerting a direct effect on the heart. The most striking result was a powerful depressant action on the conduction system, manifested by a tendency to prolongation of the P-R and QRS intervals, and leading to the development of auriculoventricular and intraventricular block. Other findings suggested some alteration in the invasion and retreat patterns of impulse spread, indicating an effect on the myocardium per se. The deleterious effects of the drug on the heart appeared to bear a close relation to the rapidity of the injection and the quantity employed; in 1 of our animals rapid intravenous administration of a relatively large dose induced a state of "chaotic heart action" with multiple ectopic pacemakers. These investigations were on experimental animals. While dosage-toxicity correlations, with respect to cardiac effects, have not been made in man, it is likely that a pharmacologic parallelism exists. The intravenous injection of procaine consequently should be undertaken with additional caution in persons with inflammatory or "degenerative" cardiac lesions.

PENICILLIN AND MALARIA

To the Editor:—I was interested to read in the Aug. 28, 1948 issue of *THE JOURNAL* an abstract from the *Indian Medical Gazette* (82:511-558 [Sept.] 1947) of an article by Deshmukh which states that penicillin seems to have a synergistic action in the treatment of acute attacks of malaria and that "penicillin controls the pre-erythrocytic stage of the malarial parasite." There is not a shred of evidence that I know of, unless one accepts the conclusions of Deshmukh, that penicillin has any effect on malaria in man. On the contrary, there is evidence that penicillin has no effect.

During the war years I had an opportunity, during studies of new antimalarials, to observe for long periods of time a great many patients with relapsing vivax malaria. Many of them were given penicillin for surgical or medical conditions other than malaria, and many suffered malarial relapses during and after administration of penicillin. So much for the pre-erythrocytic stage.

During the past year I have participated in a study of a method of inducing malaria with parasitized blood preserved by freezing. In approximately 20 cases of neurosyphilis with induced malaria penicillin was given during the incubation period and the course of the malarial attack. There was no apparent effect of the penicillin on the development or subsequent course of malaria.

GEORGE M. SAUNDERS, M.D., St. Louis.

Medical Economics

SCOTTISH EXPERIMENTS IN SOCIAL MEDICINE

A Review by Frank G. Dickinson, Ph.D.,
Director, Bureau of Medical Economic Research

The Department of Health for Scotland, under the direction of Sir Andrew Davidson, has undertaken several studies and experiments.¹ Analysis of morbidity statistics for the immediate prewar period revealed a surprising amount of chronic incapacity among the working population, particularly at ages under 40 years. Of 25,900,000 working days lost by 1,800,000 insured wage earners in the year ending June 30, 1948, 44 per cent was due to illnesses rendering 31,000 persons unfit for work throughout the entire year. Clinical data were obtained for over 50,000 patients incapacitated for three months or longer; 1,000 of these cases were subjected to intensive study. Results indicated the importance of early diagnosis and treatment in conserving the working capacity of wage earners; they also showed a need for periodic review of diagnosis and treatment in prolonged illnesses, with close cooperation between personal physician and specialist services.

AN EXPERIMENT IN PREVENTIVE MEDICINE

Early in 1942, the department instituted a program to prevent chronic invalidism by minimizing breakdown in the health of war workers. Within one and one-half years some 5,000 workers were given special clinical examination and admitted to war emergency base hospitals for detailed investigation or to country mansions for intensive convalescence. Most of these patients showed vague ill health, some degree of debility and often anxiety states due to overwork. Their response to treatment indicated the value of rest and recreation in combating fatigue which might otherwise lead to prolonged physical and mental illness.

AN EXPERIMENT IN REHABILITATION

In January 1943, the department instituted a scheme to return the sick and injured to active employment. A fitness center for disabled miners was opened; other workers were later admitted. The program consisted of activity by the patient under the direction of a physician. Average length of stay in the center is from fifty to eighty days; the discharged patient is checked by follow-ups after two and six months. Results up to June 1947 show that of 1,900 miners treated, 63 per cent were able to continue their former work, 19 per cent were fit for light work, 5 per cent were fit for alternative employment and only 1 per cent were unfit at the end of the course. Of 270 other workers treated, 69 per cent returned to their former work and less than 1 per cent remained unfit for employment. Rehabilitation methods cannot cover deficiencies in surgical or medical treatment, and must be varied with the needs of the patient. Moreover, the study indicates the rehabilitative value of returning the patient to work for which he is fit as soon as possible.

MEDICAL CARE IN A LARGE RURAL AREA

In 1912, a committee of the British Parliament made a study of medical care in the Highlands and Islands, an area including almost half of the land surface of Scotland, lying to the north and west and inhabited by 300,000 persons. Due to the sparseness and poverty of the population, inadequate transportation and communication, and geographic and climatic difficulties, medical service was uncertain for the people and hazardous for the physician. To remedy this situation, Parliament established the Highlands and Islands Medical Service Fund, under which grants were approved for (1) physicians, (2) nursing services, (3) specialist, hospital and ambulance services and (4) telegraph and telephone services. The scheme endeavors to supply necessary medical services to every person in the area and to assure each practitioner a definite minimum net income. "Scheme patients" unable to pay regular fees and not covered by the National Health Insurance scheme receive medical care

on the basis of a schedule of modified fees. To compensate for his reduced earnings, the Highlands and Islands doctor receives a yearly grant from the Medical Service Fund, along with financial aid for housing and facilities for holiday leave and postgraduate courses.

Hospital and specialist services have been developed in the area with the aid of grants from the Medical Service Fund. Ambulance services have been provided to transport patients to and from hospitals. County and district nursing associations have been organized to provide nurses fully qualified in general nursing, obstetrics and domiciliary work. Grants from the fund assure each nurse a reasonable salary, suitable residence, means of transport and telephone service.

The declared aim of the Department of Health for Scotland has been to provide necessary finance and a flexible and friendly central administration. Considerable evidence is cited to attest to the success of the Highlands and Islands Medical Service program. The standard of health in the Highlands and Islands area has risen steadily in the past thirty years. Facilities for medical care are now available to inhabitants in the most remote sections. The department has had no difficulty in obtaining qualified physicians, specialists and nurses to participate in the scheme. The Highlands and Islands practitioners have recently expressed their satisfaction with the administrative handling of the program. Judging by this report, remarkable progress has been made in the provision of medical care in this difficult and extensive rural area of Scotland.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Application of Res Ipsa Loquitur in Case of Silver Nitrate Burn.—The plaintiff sued for damages alleged to have resulted from the negligence of the defendant physician. From a judgment for the defendant, the plaintiff appealed to the district court of appeal, first district, division 1, California.

The plaintiff testified that, because of a varicose vein condition, she had visited the defendant physician and that he had directed her to enter a hospital. In the hospital the defendant had her stand beside the bed while he outlined on her legs certain veins that were to be surgically removed. The marks were made with a silver nitrate pencil which the nurse had brought to the defendant, and there were four such markings on each leg, two above the knee and two below. Shortly after the markings were put on, the plaintiff's legs began to burn and to become very inflamed around the areas marked by the defendant, and in a short time blisters formed at such areas. The pain was very severe. When the defendant physician arrived for the operation the next morning he examined her legs and told her that the operation would have to be postponed because the burns were too severe. The defendant, called as a witness by the plaintiff, admitted having made the markings on the plaintiff's legs and said that the purpose of such markings was to outline the veins to be removed. When a patient is lying down on the operating table the veins tend to relax and disappear, but when the patient is standing the veins stand out and are easily seen. The defendant said that ordinarily there is no unfavorable reaction from the application of silver nitrate but he admitted that the solution applied to some persons' legs did cause burns and that he did not know ahead of time whether or not the plaintiff was susceptible to such solution, not having made any prior test. He said that he procured the silver nitrate from the stock supply of the hospital, that he did not know who manufactured it and that he had made no attempt to ascertain that fact. He was not aware of the potency of the solution, nor did he attempt to investigate after the patient was burned to ascertain the strength of the solution. The defendant also testified that it was the common practice of doctors in San Francisco to mark off the area to be operated on with a silver nitrate solution and that it was also standard practice to mark off the operating area without first making any tests.

1. Davidson, A.: Scottish Experiments in Social Medicine, Bull. Johns Hopkins Hosp. 82: 479-495 (April) 1948.

He stated that prior to his treatment of the plaintiff he had performed three or four hundred such operations and that everything he did in this case was performed according to the ordinary standard of practice of surgeons in San Francisco.

On the basis of this evidence the trial court granted the defendant's motion for nonsuit and pointed out that the burden is on the plaintiff in such a case to show that the doctor did not possess and use the degree of skill possessed by similar practitioners in the same locality. On appeal the plaintiff urged that the doctrine of *res ipsa loquitur* was applicable to this case. The doctrine of *res ipsa loquitur*, said the Supreme Court, applies where the accident that occurred was such that in the ordinary course of events, the defendant using ordinary care, it would not have happened and where the instrumentality causing the accident was under the control of the defendant. The first requirement, continued the court, is clearly met in the instant case. Certainly it cannot be contended that the severe burning of patients is the normal result of the preparatory treatment for operation to remove varicose veins. The defendant contended, however, that the doctrine was not applicable in this case because it was not shown that the doctor had exclusive control of the silver nitrate solution, and in this connection the defendant pointed out that the evidence showed that the hospital furnished the silver nitrate pencil to the defendant. The evidence also showed, however, that the nurse asked the doctor if the equipment so furnished was what he desired and the doctor replied that it was.

After citing a number of other cases in which the doctrine of *res ipsa loquitur* was applied to malpractice proceedings the Supreme Court said that the doctrine did apply in this case and the physician was held liable. The judgment in favor of the defendant was therefore reversed.—*Hurt v. Susnow*, 192 P. (2d) 771 (Calif., 1948).

Current Medical Literature

AMERICAN

The Association Library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Mitral Insufficiency in Rheumatic Children.—The material analyzed by Kuttner and Markowitz was obtained from the records of patients who received convalescent care at a sanatorium for the care and study of children with rheumatic heart disease. Children 6 to 15 years of age, with histories of one or more attacks of rheumatic fever or chorea, were observed for various lengths of time ranging from two months to two years. Following discharge, each child was seen annually at the after-care clinic. The patients included in this study were followed for an average of eight years. The records of 315 rheumatic patients were selected for study. Group 1 consisted of 171 patients classified as having potential and possible rheumatic heart disease. These patients had soft, poorly transmitted, apical systolic murmurs and no evidence of cardiac enlargement. Group 2 consisted of 144 given a diagnosis at the time of discharge of mitral insufficiency. Of the 144 patients with mitral insufficiency, in 69 organic heart disease has developed. Of these, 13 died as a result of their rheumatic infection and 7 succumbed to bacterial endocarditis. Ninety-two of these 144 patients had a history of multiple attacks prior to the period of observation and 28 had rheumatic recurrences following sanatorium care. Of the 171 patients with potential and possible rheumatic heart disease, in 22 evidence developed of organic

heart disease. None of the children in this group died. Fifty-two of the 171 patients had a history of multiple attacks prior to the period of observation and 12 had rheumatic recurrences following sanatorium care. The striking difference between the two groups in this progression of the disease and the mortality rate indicates that the intensity of the murmur is of prognostic significance. The diagnosis of mitral insufficiency, based on a loud blowing apical systolic murmur, is justified in children, even in the absence of demonstrable cardiac enlargement.

Schemm Regimen in Congestive Heart Failure.—Newman and Stewart analyzed the diuretic effect of the Schemm regimen, which consists of a low sodium, neutral and acid ash diet, in patients with congestive heart failure. Many cases were found unsuitable for trial with the Schemm regimen. Of 30 cases originally studied, only 9 could be considered suitable for analysis, and in at least half of these complications developed which interfered at some time with the proper maintenance of the regimen. Ascites proved to be the most difficult manifestation of heart failure to treat. Seven of the 9 patients fared better on the usual regimen of restricted salt and limited fluids with frequent administration of mercuraphylline than they did on the Schemm regimen when fluids were forced and no mercurial diuretics were given. The authors say that in their experience the Schemm regimen has not been successful as a diuretic procedure in the treatment of heart failure.

Myocarditis in Pneumonia.—Saphir and Amromin studied by means of multiple microscopic sections the hearts of 67 patients with bronchopneumonia, involving at least one lobe of the lungs. Twenty-six of these revealed inflammatory changes sufficient to warrant the term "myocarditis." Fifteen were classified as acute myocarditis, 3 as acute serous, and 8 as subacute myocarditis. The outstanding clinical criteria pointing to the diagnosis were found to be: disproportion between the pulse rate and the temperature, drop in the arterial blood pressure, cyanosis out of proportion to the apparent

pulmonary involvement and unexpected death. Six of these 26 patients exhibited electrocardiographic abnormalities. Emphasis was placed on the necessity of examining multiple sections of the myocardium either to establish or to disprove a diagnosis of myocarditis.

Hormones in Treatment of Obesity.—This report by Kunde is based on the study of 50 patients with obesity. All had been referred for endocrine treatment either because of debilitating overweight, presumably due to some vague endocrinopathy, or because of some specific endocrine dysfunction with which the overweight was associated. The author stresses that no hormones or gland products are necessary adjuncts in the treatment of any type of obesity, excepting hypothyroidism. Thyroid hormones should be administered solely for the correction of a specific hypothyroidism. When this is properly accomplished, the obesity will take care of itself or it should be managed by dietary regulation. The use of thyroid extract in patients with adiposity but with no hypothyroidism, solely for the purpose of attempting to effect weight loss by stimulating metabolism, is fraught with disappointment and failure. Such overweight patients soon manifest the symptoms of severe induced hyperthyroidism with little or no weight loss. A high protein, low fat, low carbohydrate diet, supplemented with vitamins and minerals, and with no calculation of caloric values or administration of any known hormones, results in satisfactory weight reduction in all known types of obesity. Endocrine obesity is a term which is misleading in that it conveys to the obese patient a false idea, suggesting that his obesity is due to some specific endocrine glandular deficiency which can be corrected by substitution endocrine, or hormone therapy. This causes the patient to seek needless endocrine medication, whereas dietary measures and reeducation of faulty food habits are the true solutions to correction of obesity.

Protein Deficiency in Average Diets.—Soper studied for ten years 308 persons ranging from 4 to 82 years. The persons were given a complete physical examination to rule out definite medical and surgical conditions and only those who presented no obvious disease were included in this series. They were living an average life and many believed they were eating adequately, but thought it quite "un-American" to eat meat for breakfast. The occupations were largely those of the so-called white collar class and housewives, but also included a few heavy physical workers. Typical symptoms included loss of appetite, a need for eight to twelve hours of sleep, a drowsiness from arising till coffee or a cold shower had been taken. They hurried to work. Many had a feeling of well-being until about 9:30 or 10 o'clock, when a let-down occurred and a snack was needed. Lunch was eaten usually in a hurry and the patient felt fairly well till about 2 o'clock, when again he felt let down, which progressed till quitting time. Many felt so exhausted that on arriving home they had to sit and rest and often napped till time to prepare or eat dinner. Some felt best after dinner and others were so tired they felt they had to go to bed so as to be able to go to work the next morning. The author insists on a large protein serving for breakfast. It was found that any kind of lean meat, fish or fowl such as steaks, ham, pork, pork chops, lamb chops, mutton, chicken, fish, rabbit, turkey, liver or ground meats, or roasts, or cold meats, if eaten in large amounts, would suffice. Bacon has only slight value. The author stresses that the use of large quantities of meat protein up to 3 to 4 Gm. per kilogram of body weight, especially for breakfast, can do far more for the general health and strength of these patients than prolonged therapy with vitamins, iron, liver, minerals and such

Rocky Mountain Spotted Fever.—According to Muntz and Salkin Rocky Mountain spotted fever has been reported in 47 of 48 states and accounts for approximately 140 deaths annually in the United States. The disease increases in severity as one moves westward. The average figures for mortality are 25 per cent for Eastern states, 50 per cent for the Western states and 75 per cent for the Far West. On the basis of a survey of the disease in Indiana, the authors stress that Rocky Mountain spotted fever is endemic in Indiana. One hundred and ten cases have been reported in the ten-year period between 1937 and 1947. The mortality rate at the Indiana University Medical Center before para-aminobenzoic acid therapy was

33 per cent (8 deaths in 24 cases). In 8 patients treated with para-aminobenzoic acid, 1 death occurred. The disease is most prevalent in June, July and August. Any acute disease which begins with fever, chills, severe headache, pain in the bones and muscles and a macular eruption which becomes petechial after recent contact with ticks should be strongly suspected of being Rocky Mountain spotted fever. The authors believe all patients with Rocky Mountain spotted fever should be treated with para-aminobenzoic acid. Routine symptomatic care and antibiotic drugs are valuable adjuncts to prevent secondary infection in the debilitated patient. The specific vaccine for Rocky Mountain spotted fever should be considered as a possible method of prophylaxis.

Clinical Diagnosis of Fat Embolism.—According to Newman fat embolism occurs in a high percentage of all cases of injury. It is a relatively frequent complication of fractures of the long bones in civilian accidents as well as battle casualties. The diagnosis can usually be established by the clinical features together with certain physical signs which must, however, be sought deliberately. Important clinical features are mental changes such as failure to cooperate, restlessness, delirium, stupor, alternation of coma with full consciousness, petechial hemorrhages in the conjunctiva and skin, particularly in the supraclavicular regions, and typical changes in the retina. Evidence is still conflicting as to whether the fat arises by embolism from an injured bone or by general metabolic disturbance. The fat is harmful not so much by reason of mechanical obstruction of vessels as by erosion and rupture of the vessel wall due to the liberation of fatty acids. Preventive treatment includes protection from long journeys over rough roads and care to avoid unnecessary manipulation. It appears to be of some value but no satisfactory specific treatment is yet available for the established case. Ligation of the profunda vein as a means of arresting venous drainage from the area of the femur has been tried in 2 patients, one of whom recovered and the other died.

Traumatic Uremia.—Darmady believes that traumatic uremia is of particular significance to orthopedic surgeons so far as this complication is responsible for high mortality in severe injury, crushing injury, traumatic shock, gun shot wounds, incompatible blood transfusions and the misuse of tourniquets. The association between muscle injury and renal failure is reviewed. The syndrome of the "crush kidney," which at first was thought to be the result of deposition of myohemoglobin in the renal tubules, is almost certainly due to the association of many factors all of which lead to alteration of the renal circulation and renal ischemia. Ischemia of the kidney combined with deposition of pigment and hemolysis of blood causes a high mortality in animals. This may account for the serious prognosis in man where there is both shock and hemolysis. Disturbance of water balance, allergic phenomena and chemical nephrotoxic action are discussed as other possible etiologic factors. Necropsies revealed that probably the only characteristic change of the syndrome of traumatic uremia is in the kidney itself, which is increased in weight. The greatest changes occur in the loops of Henle. There is a wide variety of casts which tends to obscure the tubular degeneration. One of the most interesting features is the occurrence of venous thrombi in the boundary zone associated with rupture of the tubules into the veins. A plea is made for early clinical recognition of the syndrome with its characteristic features, such as vomiting,

oliguria, hypertension with rapid and pronounced rise of blood urea or nonprotein nitrogen. Important aspects of treatment such as correction of electrolyte balance, management of water metabolism, use of sodium sulfate, artificial kidney, peritoneal dialysis and renal decapsulation are discussed. The dangers of excessive intravenous infusion are emphasized.

Concentrated Human Serum Albumin in Hepatic Cirrhosis.—Kunkel and his associates report the results of albumin therapy in 17 patients with severe hepatic disease. All but 2 of them had ascites at the time when albumin was first administered. In 9 of 15 patients with fluid retention who were treated, a rapid loss of edema and ascites occurred. Five others showed a delayed loss of ascites. In those patients whose diuretic response to albumin was immediate, a beneficial course of events was rapidly initiated; loss of protein into ascitic fluid ceased, dietary protein intake increased, and positive nitrogen balance resulted. Such treatment carried seriously ill patients through the early critical period of their disease until such time as dietary and liver extract therapy had an opportunity to take effect. The amount of albumin needed to produce a loss of ascites was extremely variable, ranging from 4 to 80 units. Patients with evidence of portal obstruction, a high antidiuretic titer in the urine or long-standing ascites proved unresponsive to therapy. Patients with particularly severe hepatic disease and low plasma albumin levels following infectious hepatitis responded most readily to therapy. Patients having alcoholic and nutritional cirrhosis with a short period of ascites also responded to relatively small doses of albumin. Permanently beneficial results were obtained in 6 of 7 patients with the nutritional type of cirrhosis. Two of these patients required a second short course of therapy. Patients with post-necrotic cirrhosis after infectious hepatitis and biliary cirrhosis showed only a temporary response, and 4 of these patients eventually died. Evidence was presented for certain specific effects of serum albumin on dietary intake and nitrogen balance which may be of greater importance in the results obtained than its osmotic properties.

Effect of Calcined Alumina on Health of the Workmen.—Meiklejohn and Jones point out that inhalations of small amounts of suitably prepared pure aluminum metal, for short periods each day, have been used to inhibit toxic effects of silica in the lung and thereby delay, if not altogether prevent, the production of silicotic fibrosis. It occurred to the authors that a practical field test of the efficacy of one form of alumina in the treatment and prevention of silicosis had been in progress, over a period of years, among certain workmen in the pottery industry employed in the "placing" of china ware for the biscuit firing. Until 1929 finely powdered calcined flint was the medium in general use for this process, but later there was a gradual change over to the use of calcined alumina (Al_2O_3). The authors review observations on 52 china biscuit placers who had previously been examined by the medical board. All had considerable previous exposure to flint, followed by daily exposure to alumina varying from two to sixteen years. All the workmen were convinced that alumina produced a dustier atmosphere than flint, but all were agreed that alumina did not irritate the nose and throat or induce the feeling of stuffiness on the chest so familiar to them with flint. The old fear of the "dust" had gone. Even so complaints of cough, expectoration and dyspnea were as frequent as before. When flint was the medium the china biscuit placer was pale, often haggard and listless, but now he appeared natural in complexion, robust and active. These workers were reexamined. It was found that although this group of workmen were daily exposed to finely powdered alumina in a greater intensity and over a considerably longer period than is possible by existing methods of aluminum prophylaxis and therapy, not only did new cases of silicosis occur but known cases advanced. The authors think that ten or twenty years must elapse before any authoritative opinions on the subject can be expressed, and that reports based on short term observations should be treated with circumspection.

Cerebrospinal Fluid.—The observations presented by Hassin on the complex problem of the origin, absorption and circulation of the cerebrospinal fluid are based chiefly on neuropathologic observations, experimental data being referred to only for comparison. He concludes that the cerebrospinal fluid represents the tissue fluids of the brain. The contents of the Virchow-Robin spaces which originate in the tissue fluids and which are discharged into the cerebral ventricles and the sub-arachnoid spaces are a part of the cerebrospinal fluid. The absorption of the cerebrospinal fluid is effected not through the villi or pacchionian bodies but through the perineurial spaces of the cranial nerves and spinal roots. The function of the choroid plexuses is not to secrete fluid but to excrete or eliminate from it noxious substances and to make it absorbable by the perineurial spaces. The cerebrospinal fluid is a lymph of the central nervous system, for it carries away its waste. There is no circulation of the cerebrospinal fluid under normal conditions. The collapsing and expanding movements of brain and spinal cord represent the forces that facilitate removal of the spinal fluid. The Virchow-Robin spaces represent the hemato-encephalic barrier.

Kernicterus.—Becker and Vogel describe 7 cases of kernicterus, all of which were associated with erythroblastosis fetalis. The condition was confirmed by serologic and histologic studies. In cases 1, 2, 3, 5 and 7 the infants were Rh positive and the mother Rh negative with anti-Rh agglutinins. In case 4, the erythroblastosis was presumably due to the A factor. In case 6, the erythroblastosis was due to the Rh" factor. In 5 cases jaundice appeared during the first day of life; postmortem studies disclosed the discoloration to be present most frequently in the hippocampus, basal ganglions, midbrain, medulla and floor of the fourth ventricle. In regions grossly bile stained the nerve cells were shrunken and stained readily with eosin, some containing dark-staining nuclei. Some nerve cells displayed poorly stained cytoplasm and vacuolization. Extramedullary erythropoiesis, chiefly in the liver and spleen, and visceral hemorrhages were other anatomic findings.

*Diagnosis and Treatment of Scabies. E. A. Hand.—p. 519.

Diagnosis and Treatment of Scabies.—Hand says that the normal decrease in scabies expected in the summer of 1946 did not occur. This was the result of the demobilization of infested army and navy personnel, pouring fresh scabies into the civilian population. The summer of 1947 saw the normal decrease, but the disease is again on the increase. Friedman noted that the acarus could easily be demonstrated by the scrape and smear method, and also that the diagnosis could be made by finding acarus eggs filled with embryo or empty, skeletal parts of the acarus, the larvae, and the scybala as well as from the adult acarus. Scabies should be suspected in all cases of furunculosis, as this often masks the underlying scabies. This is also true of ecthyma, pyoderma and impetigo in children. The following

areas should always be examined: the webs of the fingers, the anterior portion of the wrist, the inner and posterior part of the elbows, the anterior axillary folds, the nipples and breasts in women, the navel and abdomen, the shaft and glans penis in the circumcised, the penis shaft to the external rim of the foreskin in the uncircumcised, the scrotum, the buttocks, and the knees, ankles and toes. Though scabies is more common in the poor and unclean, it is found in all classes and in all periods of life. Next to avoidance of those infested, frequent bathing is the best prophylaxis. Sulfur has been used in many forms, but benzyl benzoate is the treatment of choice for scabies.

Prevention of Cold.—The study reported by Cowan and Diehl was conducted at the request of the Commission on Influenza of the Office of the Surgeon General, U. S. Army. The experimental subjects were students of the University of Minnesota. A controlled study indicates that influenza vaccine A and B is of no value for the prevention of the common cold. The subjects who received influenza vaccine reported more reactions than the control group.

Portacaval Shunts in Portal Hypertension.—Linton presents 4 cases in 3 of which the results obtained in the treatment of portal hypertension, secondary to an extrahepatic portal bed block (Banti's syndrome), by the formation of portacaval shunts were encouraging, since none of the patients with satisfactory shunts has bled since they were performed. The most satisfactory portacaval shunt seems to be an end-to-side suture type of splenorenal anastomosis performed at the same operation at which the spleen is removed. In some patients who have had previous splenectomies it may be possible to perform other types of portacaval shunts, such as a superior mesenteric vein to inferior vena cava or inferior mesenteric vein to left ovarian

vein. Two patients have gone twenty-two and fourteen months since the shunts were formed without evidence of esophago-gastrointestinal hemorrhages. A direct portacaval anastomosis was not possible in 3 of these cases because of a cavernomatous transformation of the portal veins. It is believed that a surgeon should not do a splenectomy in a case of portal hypertension unless he is prepared to do a splenorenal anastomosis at the same operation, since this may be the only opportunity to construct a satisfactory shunt. A longer period of observation is necessary to determine whether the portal hypertension and the tendency to esophagogastrointestinal hemorrhages have been permanently influenced.

Pain in Leukemia Simulating Rheumatic Fever or Endocarditis.—Aisner and Hoxie report 4 cases of acute lymphatic leukemia, 3 of which presented signs and symptoms simulating those of acute rheumatic fever and 1 simulating those of subacute bacterial endocarditis. The authors discuss certain pitfalls and aids in the differential diagnosis between acute rheumatic fever and acute lymphatic leukemia. Complete examination of the blood should be performed routinely in all cases presenting bone or joint pains. The findings that point to the diagnosis of lymphatic leukemia rather than of acute rheumatic fever are leukopenia persistent in the presence of an active clinical course, leukopenia or leukocytosis associated with an increase in the percentage of lymphocytes and bone changes on roentgen examination. The authors enumerate the various bone changes in leukemia that are visible by roentgen study and stress the differential diagnostic importance of other disorders that cause bone and joint pain in young persons.

Results of Vagotomy.—Blackford and McCausland report on 22 vagotomies, 12 of which were performed by the trans-abdominal route in combination with other procedures and 10 of which were done by the transthoracic route without other surgery. In one instance a transthoracic vagotomy was followed two months later by a subtotal gastrectomy with further resection of the vagus nerves. In the 12 patients subjected to trans-abdominal vagotomy the ulcers were either duodenal or marginal. Vagotomy was combined with subtotal gastrectomy six times, with posterior gastroenterostomy five times, and in 1 case the stomach was opened and the pylorus manually dilated. A three to eleven months follow-up period revealed that results were excellent in 10, good in 1 and poor in 1. There is still insufficient evidence that vagotomy will prevent formation of a subsequent marginal ulcer. Improvement may be the result of the supplementary gastric surgery rather than of vagotomy. Trans-abdominal vagotomy combined with other gastric surgery must be considered at this stage of clinical experimentation. Transthoracic vagotomy gave equivocal results in the 10 cases reported. In only 6 of the patients have the results been entirely satisfactory. Three patients came to a subsequent subtotal gastrectomy. As yet no criteria have been found by which one can judge which patient having ulcer with pain will be relieved

permanently by a simple vagotomy. Until one can predict this and until one knows late results in a large series of cases the authors intend to employ a simple vagotomy with considerable caution.

Rhinosporidiosis of Conjunctiva.—Edmunds and Beck report a case of rhinosporidiosis of the conjunctiva in a white boy aged 12 years. The external appearances of both eyes were normal. When the lower lid of the left eye was everted there was a reddish partially sessile growth originating from the conjunctiva of the lower lid in its outer third. The growth was painless and measured about 6 mm. by 6 mm. by 8 mm. Complete excision and removal of the growth followed by cauterization of the base would seem the best treatment so far available. Microscopic examination of the growth showed a papilloma with little papillary branching or crypts. The striking observation was the presence of numerous round, thick-rimmed, double contoured, sharply defined cystic bodies of various sizes in the stroma of the growth. There was a moderate round cell infiltration around some of the medium-sized cystic bodies and the stroma of the polyp was moderately vascular. These cystic bodies are the trophic stages and immature and mature sporangia of *Rhinosporidium secheri*. The spores can be seen being liberated from the sporangium, anywhere in the interstices of the stroma of the polyp, occasionally in the macrophages and in the epithelium. Rhinosporidiosis is a local fungous infection of the mucous membranes with predilection for those of the nose and conjunctiva, caused by *Rhinosporidium secheri*. The mode of infection is not known. While this disease appears rather rare, perhaps more cases would be found and diagnosed if more polypoid growths of the nasal mucous membrane, conjunctiva and pharynx were submitted to the laboratory for microscopic study.

Pregnancy and the Thyroid.—Peters and his associates point out that while it is generally agreed that the thyroid gland undergoes hyperplasia during pregnancy, there is no certainty that this hyperplasia is attended by hyperfunction. The rise of basal metabolism in pregnancy is not accompanied by other recognized manifestations of hyperthyroidism. Serum cholesterol is said to increase, a phenomenon that is regularly observed in hypothyroidism. Clinical hyperthyroidism may begin during pregnancy, but this does not seem to be a frequent occurrence. The authors are concerned chiefly with the concentrations of precipitable iodine in the serums of pregnant women. They found that precipitable iodine of the serum rises sharply at the onset of pregnancy from the normal concentration of 4 to 8 micrograms per hundred cubic centimeters to concentrations between 6 and 10 micrograms, and remains at these levels until delivery, after which it rapidly returns to the normal range. This rise is not accompanied by other manifestations of increased activity of the thyroid gland. There is reason to identify the increment of iodine with the thyroid hormone. There is evidence to suggest that failure of the precipitable iodine to rise at the onset of pregnancy leads to early miscarriage which may be prevented by the administration of active thyroid substance. Low precipitable iodine in these cases is not accompanied by other manifestations of thyroid deficiency. The serum-precipitable iodine in pregnancy does not appear to be consistently related to the concentration of iodine preceding pregnancy. No evidence has been found that serum-precipitable iodine is abnormal in women with infertility or toxemias of pregnancy.

Synopsis of Pediatrics. By John Zahorsky, A.B., M.D., F.A.C.P., Professor of Pediatrics and Director of the Department of Pediatrics, St. Louis University School of Medicine, St. Louis. Assisted by T. S. Zahorsky, B.S., M.D., Senior Instructor in Pediatrics, St. Louis University School of Medicine. Fifth edition. Fabrikoid. Price, \$5.50. Pp. 449, with 167 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

In the fifth edition of this well known volume of pediatrics, some minor alterations have been made in keeping with recent advances. Some of the newer drugs are only mentioned; i. e., diphenhydramine ("benadryl"). There are 158 text illustrations, of which many are from the original edition. Some of these are obsolete, as for example the illustration of the technic for intramuscular injection of blood into the buttocks in hemorrhagic disease and icterus gravis. This present edition will continue to be a most practical and useful manual for the busy general practitioner.

Psychotherapy: Its Uses and Limitations. By D. Rhodes Allison, M.D., M.R.C.P., and R. G. Gordan, M.D., D.Sc., F.R.C.P. Oxford Medical Publications. Cloth. Price, \$3. Pp. 160, with 1 illustration. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E.C.4, 1948.

The aim of this book is well stated in the preface. The authors have, they say, "tried to point out how without special knowledge the physician and the family doctor may often help the patient to conquer his disease by maintaining his courage and morale, and have urged the necessity, if medicine is to progress, that an end should be made to suspicions and rivalries and that all branches of medicine should combine to fight disease in a team which can deal with both psyche and soma with individual and environment, all of which indeed are indivisible." Some of the chapter headings are: psychosomatic conditions, the relation of rheumatism to mental illness, psychotherapy in the treatment of psychoses, the patient's reaction to bodily disease, and the combined approach.

The authors recognize the value of psychotherapy in certain well selected cases, pointing out that it is no panacea, that no one method is applicable to all cases, and that the personality as well as the training of the therapist is important. They point out, too, the fallacy of blaming on the patient's "uncooperativeness" any failure of therapy; instead, they say, "it is the business of the doctor to determine, if he possibly can, why the patient cannot or will not cooperate, and in the case of the psychoneurotic, to resolve the difficulty or to hand the patient over to some one who can do so [p. 148]." The authors write well, with eminent British common sense and broadness of view. The book can be recommended to every physician interested in the field of treatment.

Chaucer's World. Compiled by Edith Rickert. Edited by Clair C. Olson and Martin M. Crow. Cloth. Price, \$6.75. Pp. 456, with illustrations selected by Margaret Rickert. Columbia University Press, 2960 Broadway, New York 27, 1948.

This scholarly volume began with the research of the late Professor John M. Manly and Edith Rickert on Chaucer and Chaucer's times. The book includes a collection of documents, quotations, diaries, notebooks and all sorts of other memorandums which afford a fascinating reflection on the times concerned. A section dealing with the ethics of the physician has already been quoted in the Tonics and Sedatives column of *THE JOURNAL*. There are several other medical items of similar interest. Most of the quotations in medicine come from the famous John Arderne, who was born in 1307 and whose work seems to have been personally known to Chaucer. There is record of a case of malpractice for wrongly setting an arm with a claim for damages of 200 pounds. The record of the Court of Common Pleas of the London of that period seems to have involved the doctors rather frequently.

Barbed-Wire Surgeon. By Alfred A. Weinstein, M.D. Cloth. Price, \$3. Pp. 310. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

In 1940 Dr. Alfred A. Weinstein joined the United States Army. Thereafter he was nearly three and one-half years in prison, sometimes in hospitals, under the none too gentle care of the Japanese. Reports indicate that some 18,000 were under these tender ministrations but about 4,000 survived to return home. The record by Dr. Weinstein is an account of the situations in which he took an actual part. It is full of incidents and anecdotes with a medical flavor and it will serve to remind

both those who fought and those who remained at home that the brutalities of the Far East were quite as vicious as those of middle Europe and had their own peculiar flavor as well. As the author says in his prologue, this is the story of GI Joe in prison, a story of hunger and disease, in which the personal problems of the author serve to carry the thread of the story from beginning to end.

Life is for Living. By D. Ewen Cameron, M.D., Professor of Psychiatry, McGill University, Quebec. Cloth. Price, \$2.75. Pp. 241. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

The trend toward writing interpretive books for lay people continues. However, the quality of many of these works is so poor that the lay reader becomes more confused than settled in his thinking. Dr. Cameron apparently is the newest aspirant to attempt to climb the bandwagon of popular psychiatric works. His title is intriguing, but his material is disappointing. He states that he has written a book for those of us who are trying to grope our way through the confusions and contradictory absurdities, the moral dangers and the psychologic pestilences of midcentury living. The organization of the book is in itself confusing, because there seems to be no planned continuity in the development of his concepts. At certain points the text is even incoherent. He raises many questions and then goes off into rambling, philosophical answers which could not satisfy even the most learned seeker for stability. The author uses the text to present some of his favorite concepts without documentation. The book does not have either index or bibliography. The author closes with a trite statement that "what we must do is to see our world. . . in which we must at last take final responsibility for ourselves, in which all man's works will be his works."

Symposium on Medicolegal Problems Under the Co-Sponsorship of the Institute of Medicine of Chicago and the Chicago Bar Association. Edited by Samuel A. Levinson, M.D., Ph.D., for the Committees of the Institute of Medicine and the Chicago Bar Association. Fabrikoid. Price, \$3. Pp. 255. J. B. Lippincott Co., 227-231 S. 6th St., Philadelphia 5, 1948.

The Institute of Medicine of Chicago and the Chicago Bar Association collaborated in 1945 in arranging a symposium on medicolegal problems. Six subjects were selected for discussion, and the medical and legal aspects of each subject were presented respectively by a physician and by an attorney, followed by a question and answer period. The subjects chosen were The Medical Witness in Court, Artificial Insemination, The Practice of Pathology and Its Medicolegal Problems, Operations to Produce Sterility, Trauma and Tumors in Industrial Medicine, and Scientific Tests in Evidence, such as blood grouping tests in disputed paternity cases and chemical tests for intoxication. This small volume contains the twelve papers that were presented and the discussion that followed the presentations. These papers are most informative, and the symposium concretely reflects the value of meetings between groups of physicians and lawyers for discussions of oftentimes perplexing problems of mutual interest. Physicians, lawyers and others interested in this particular field will find in these papers much of value and answers to many questions that cannot be found conveniently elsewhere.

An Introduction to Clinical Psychology. Edited by L. A. Pennington, Ph.D., Associate Professor of Psychology, University of Illinois, Urbana, Illinois, and Irwin A. Berg, Ph.D., Associate Professor of Psychology, Pomona College, Claremont, California. With a foreword by George D. Stoddard, Ph.D., President of the University of Illinois, Urbana. Cloth. Price, \$5. Pp. 395, with 42 illustrations. The Ronald Press Co., 14 E. 26th St., New York 10, 1948.

The authors point out that the variations in what clinical psychologists individually do accounts for marked differences in content of courses labeled "clinical psychology." There are many state certification laws which require academic credit for a course in clinical psychology. Yet students who meet this requirement frequently secure widely differing training in different institutions. Such courses may actually be those of advanced abnormal psychology, psychologic and clinical testing or a minor course in counselling and psychotherapeutic technics. Still a fourth course may be concerned solely with personality development. The aim of this book is in a sense to alleviate these difficulties and present a first course in clinical psychology, including a definition, meanings of concepts, a discussion of

behavior problems, presentation of the tools with which the psychologist works, a description of minor therapeutic procedures by which behavior disorders can be alleviated and a discussion of professional relationships between psychologists and members of the psychiatric profession and their mutually overlapping fields.

Certain sections of the discussion revolve about the problem of where the field of the psychologist ends and that of the psychiatrist begins. The authors appear to hold to the view of nonlimitation of the field of the psychologist, which is directly in contradistinction to the attitude of most psychiatrists and psychoanalysts. Most psychiatrists feel that the function of the clinical psychologist in therapy of mental disease is to render assistance to the psychiatrist, rather than to assume his whole function. The volume is otherwise excellently conceived and provides a comprehensive coverage of clinical psychology, especially for the student. Fifty-six useful illustrations and reference tables are included.

A Textbook of Clinical Pathology. Edited by Francis P. Parker, M.D., Associate Professor of Pathology, University of Virginia School of Medicine, Charlottesville, Virginia. [Formerly edited by Roy R. Kracke and Francis P. Parker.] Third edition. Fabrikoid. Price, \$9. Pp. 1023, with 228 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

This new edition represents a revision of the previous one by Kracke and Parker. The contents are made up of contributions by eight authors, all authorities in their branches of clinical pathology. As in previous editions, the interpretation of laboratory findings is the most distinctive feature and is of special value to practitioners.

The chapter on blood includes technic and findings of bone marrow studies. In the discussion of hemorrhagic diseases the procedures helpful in diagnosis and treatment are well described. Blood groupings and Rh factors are particularly well discussed and brought up to date. The section on clinical chemistry emphasizes the common determinations, including phosphatases, total proteins, sodium and potassium. Short chapters on an assay of hormones and vitamins have been included. Tests for hepatic function, including the valuable cephalin-flocculation and alkaline phosphatase tests, are assembled separately. Sputum examinations are well illustrated and include examinations for fungi and the fluorescent demonstration of acid-fast organisms.

In a brief chapter, the tests for renal function are presented in clear, simple form. Illustrations of slide and tube agglutinations, cutaneous reactions in allergy and brucellosis add to the clear, comprehensive presentation of immunologic tests in disease.

With reference to the serologic diagnosis of syphilis, the additional procedures like the Mazzini slide test and Boerner-Lukens complement fixation test are described. Biologic false-positive reactions and their interpretation are discussed.

In the appendix is a valuable description of the common bacteriologic technical methods employed in a hospital laboratory. Each chapter is supplemented, in most instances, by an adequate bibliography.

The book is recommended to students and practitioners as well as laboratory personnel for its interpretive as well as informative contents.

Neuroanatomy. By Fred A. Mettler, A.M., M.D., Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University, New York. Second edition. Cloth. Price, \$10. Pp. 536, with 357 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3, 1948.

This is the second edition of a work which first appeared in 1942, a fact which is ample evidence that the book has met with approval. The book is divided into two sections. The first half deals with the gross anatomy of the nervous system, exclusive of the peripheral nerves. The sympathetic system is briefly discussed. The second half is concerned with the microscopic organization of the nervous system and a limited correlation of structure with function. The facts of neuroanatomy are, for the most part, presented accurately. They are not always readily available and their relationships and significance are often not made apparent to the beginning student, for whom the book is written. The index contributes to the difficulties in locating the desired information. Many titles have a large

number of pages cited without any qualifying references; the vagus nerve has 59, the medial lemniscus 54 and other titles almost as many. With these the reader can waste much time before locating the principal discussions. Furthermore, the discussions of many subjects have been divided between a number of different places. Much of the discussion of the detailed structure of the central nervous system, notably the brain stem, is by description of successive serial sections. These are detailed and accurate. However, the attempted correlation of this information is so incomplete that the student must have difficulty in appreciating the organization of any extensive system. In not a few places the discussions are unduly complicated and at the same time deficient. The description of the gross anatomy of the trigeminal nerve on page 81, of the inter-trigeminal foramina of Monro on page 104 and of the efferent and afferent connections of the cerebellum on pages 326 to 327 are cases in point. The extensive, careless use of inaccurate contractions of terminology, characteristic of the dissecting room and laboratory, detracts from the book. Examples of this are the repeated use of "dura" for "dura mater," of "callosum" for "corpus callosum" and of "medulla" or "oblongata" for "medulla oblongata." There are a few obvious errors, such as the following: the trigeminal (or gasserian) ganglion does not lie in the floor of the cavernous sinus (page 81). The posterior commissure does not end in the pineal body (page 100). The rubrospinal tract in man is not comparable to that in lower animals as the student would probably conclude from page 345. The origin of specific extrapyramidal corticofugal pathways is not discrete and sharply localized as is indicated in figure 263A. This work is profusely illustrated. There are a number of clear, illustrative photomicrographs, and 46 pages of well chosen references to the literature.

American Universities and Colleges. Edited by A. J. Brumbaugh, Vice President, American Council on Education, Washington, D. C., and Mary Irwin. Fifth edition. Cloth. Price, \$8. Pp. 1054. American Council on Education, 744 Jackson Place, Washington 6, D. C., 1948.

Among the most valuable of the reference books available in the field of education is this standard guide first inaugurated in 1928 and thereafter published at four year intervals. The book is up to date and includes complete facts regarding 820 educational institutions with all of the information that the average student or any one else in the educational field would wish to have. The appendixes provide full information concerning the American Council on Education and other educational associations, information concerning academic costumes and accepted abbreviations for degrees. There is also an extensive general index, institutional index and a series of classifications by geographic and other divisions.

Directory of Physicians Interested in Clinical Allergy. Compiled by Jonathan Forman, B.A., M.D., F.A.C.A. Fabrikoid. Pp. 176. The Compiler, International Correspondence Society of Allergists, 956 Bryden Road, Columbus 5, Ohio, 1948.

This book contains a list of physicians who devote all or a part of their time to the treatment of allergic patients. The names are listed by states, cities and countries. The compilers admit that there may be omissions and welcome additions, corrections and suggestions for the next edition. Brief data concerning membership in professional societies accompany many of the names. The two indexes in the back comprise an alphabetical list of allergists in the United States and an alphabetical list of allergists in other countries. The several full page advertisements might well have been placed at the front or back of the book.

Taking the Cure: The Patient's Approach to Tuberculosis. By Robert G. Lovell, M.D. Cloth. Price, \$2. Pp. 93, with 6 illustrations by Donald Gooch. The Macmillan Company, 60 Fifth Ave., New York 11, 1948.

This booklet is packed full of sound advice for the tuberculous patient from one who has been through the mill. It has a special appeal in its brevity, its coverage of pertinent information and advice and its all-around excellence of quality. It is easily readable and may serve both the well read and those of more limited cultural attainments. The message is punctuated by a few well placed and impressive caricatures. There is also a useful bibliography for tuberculous patients which in reality will serve every type of human mentality.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VITAMIN C IN ACUTE RHINITIS

To the Editor:—Massive doses (1,000 mg. the first day; 700 mg. the second) of ascorbic acid have been recommended in the early stages of acute coryza, and the claim has been made that an acute cold may be aborted by this form of therapy. Is there evidence either for or against this form of therapy? Do harmful effects occur from therapy with ascorbic acid in the mentioned dosage?

M.D., New York.

ANSWER.—A few years ago several articles appeared which advocated use of large doses of ascorbic acid in the early stages of acute rhinitis. Subsequently little evidence has appeared to support the contention that this therapy has any appreciable effect in aborting or cutting short the attack. Personal experience also fails to support the claim. Harmful effects have not been reported or experienced by the writer. More recently the use of tripeleminamine hydrochloride or other antihistaminic drugs has been recommended in the early stages of acute rhinitis on the assumption that vasodilatation responsible for the free flow of nasal secretion could be controlled by these drugs. Beneficial effects are reported by a few persons, but controlled statistics are not as yet available.

CATALEPTIC RIGIDITY

To the Editor:—A school of hypnology (so-called) issues a prospectus wherein there is a picture of a 235 pound (106.6 Kg.) man standing on a 113 pound (51.3 Kg.) woman in a cataleptic state supported by her heels and her head. Must I believe this? Would she support a ton? For how long? We know that a certain degree of tense rigidity can be secured in a cataleptic state but surely the cataleptic patient cannot become as rigid and strong as a plank of hard wood.

Max Isenberg, M.D., New York.

ANSWER.—Under deep hypnosis a subject can be given the suggestion that he will become rigid and the subject's body will retain the position in which it has been placed for a considerable time, even when the attitude is one which is difficult to maintain. It is quite possible that a woman of 113 pounds could support, in a cataleptic state, a man of 235 pounds for a few seconds. Under continued tension the muscles of course may eventually give way. This would depend on the musculature of the individual. Although a subject may remain rigid indefinitely this rigidity would not be maintained under a great weight. Such a person would not be able to support a ton, and no person would likely be able to maintain twice his or her weight more than a few seconds. The potential strength of the subject's muscles and bones would be the determining factor, and not the hypnotized will.

LEAD POISONING AND ARTERIOSCLEROSIS

To the Editor:—A patient, 58 years of age, has had chronic lead poisoning of eight to ten years' duration. There is a history of a lead line, typical colics, weakness, peripheral pain without paralysis, typical blood picture and normal blood pressure without evidence of renal involvement. The urine has always been entirely normal and there has been no peripheral edema. A few years ago symptoms of a peripheral occlusive vascular disease of the right leg developed which was diagnosed elsewhere as Buerger's disease and also as endarteritis obliterans. A progressive change occurred which led to gangrene requiring amputation. Now it is claimed that the occlusive vascular disease which required the amputation was due to the chronic lead poisoning. It is my understanding that this does not occur in lead poisoning without associated renal damage. Allen, Barker and Hines in their book "Peripheral Vascular Diseases," page 357, stated, "certainly lead poisoning cannot be considered to be a factor in the great majority of cases of arteriosclerosis and there is considerable question as to whether it ever produces typical arteriosclerotic lesions." Does chronic lead poisoning with normal renal function and normal blood pressure ever produce a peripheral occlusive vascular disease sufficient to cause gangrene requiring amputation?

William W. Leake, M.D., Chicago.

ANSWER.—It is highly unlikely that lead causes arteriosclerosis or accentuates an existing one. Persons exposed to a lead hazard do not appear to have more arteriosclerosis than similar groups of workmen in other trades. As in this patient, the blood pressure appears unaffected by lead poisoning. Arteriosclerotic gangrene is not a manifestation of lead intoxication.

SIZE OF BRAIN

To the Editor:—Please send me details of method of calculating size of living brain based on three linear dimensions of head, as described in Berry's "Brain and Mind," Macmillan, 1928.

M.D., Pennsylvania.

ANSWER.—Berry's method is to obtain measurements of (1) length of head; this is a caliper measurement from the most prominent point of the glabella to the most distant point in the midline at the back of the head; (2) breadth of head, the greatest distance obtainable by the calipers applied to the parietal eminences; (3) height of head, the highest point of the cranium vertically above the center of the external auditory meatus; these measurements are in millimeters and are applied to the following formula:

$$\text{Brain capacity} = 0.000337 \times (\text{length} - 11 \text{ mm.}) \times (\text{breadth} - 11 \text{ mm.}) \times (\text{height} - 11 \text{ mm.}) + 406.01$$

The subtraction of 11 mm. from each of the three measurements is the allowance made for the thickness of the skull and the over-all soft parts. The multiplication of the first four numbers with the addition of the fifth is believed to give the capacity of the brain in cubic centimeters.

TULAREMIA ENCEPHALITIS

To the Editor:—A patient had early papilledema, some sensory changes and a tendency to weakness of the left side of the body. Brain tumor was diagnosed and the patient was referred to a neurosurgeon. Diagnosis was confirmed and operation performed. Nothing was found except encephalitis which was believed to be due to an old case of tularemia. What treatment can be given this man? Would any of the biologicals such as streptomycin offer hope? Would roentgen therapy be of benefit?

Ben Raney, M.D., Linton, Ind.

ANSWER.—Infection of the brain in tularemia has been reported, but in this region of the country it must be rare. The difficulty would lie primarily in substantiating such a diagnosis. Localized encephalitis from other sources has been confused with tumor for the reason stated in the question. However, encephalography, or, what would be probably better in this case, ventriculography, would have ruled out a space-occupying lesion. As far as is now known, neither streptomycin nor high voltage roentgen therapy would be of any avail against the bacillus of tularemia. The best treatment would probably be attention to general health and hygiene with, perhaps, iodides in fairly large doses.

HEREDITY OF BIRTH MARKS

To the Editor:—Recently a young primiparous woman gave birth to a female infant with a "port wine stain" occupying the entire lateral surface of right foot, leg, vulva and sacral area. The baby was otherwise normal. The mother is considerably upset over this birth mark and has asked for sterilization, even though the couple desires more children. Neither parent nor known relatives have birth marks. What are the chances of a second baby's having similar marks?

Louis N. Speer, M.D., Ottawa, Kan.

ANSWER.—Birth marks or nevi are of many different types. Some of them have been shown to have some hereditary basis, occurring at times in three or four generations. Cockayne, "Inherited Abnormalities of the Skin and its Appendages," (New York, Oxford University Press, 1933) is a good source for detailed information on the subject. Many cases of birthmarks, of the type described, however, appear singly in families; i. e., without evidence of a hereditary basis. Therefore it appears reasonable that the probability of a second child's showing a similar condition is low. Sterilization is hardly indicated.

SPERMATOZOAN IMMUNITY

To the Editor:—A patient requests information on the possibility of temporary sterility of the wife by injection of the husband's semen. I have never heard of the idea and knew nothing of it. Neither have several gynecologists whom I have consulted.

M.D., California.

ANSWER.—A good deal of experimental work has been done on animals with the aim of producing a so-called sperm immunity in the female. Injection of spermatozoa, both from the same and from other species, has evoked antibodies which can immobilize and agglutinate spermatozoa in vitro. But in most of the experiments reported the female animals thus "immunized" have continued to breed with undiminished fertility.

A few similar attempts have been made in human beings, with generally inconclusive results. Since neither the degree nor the duration of the possible immunity to pregnancy can be predicted, this method would appear to be among the most unreliable of contraceptive technics.

PNEUMOTHORAX IN PNEUMONIA

To the Editor:—Could pneumothorax be the cause of death in a patient 45 years of age who died twenty-six days after the onset of lobar pneumonia?
W. B. Shore, M.D., Anchorage, Alaska.

ANSWER.—Pneumothorax could be the cause of death of any one regardless of age, or of immediately preceding pneumonia, as a result either of the so-called pleural shock or of extreme displacement of the mediastinum; and in pneumonia or other disease, by reducing further the available amount of aerating lung tissue. Atelectasis during lobar pneumonia is not uncommon, but pneumothorax is rare and occurs chiefly as a result of perforation by secondary pulmonary abscess or empyema. An instance of spontaneous pneumothorax during pneumonia is illustrated in "The Pneumonias," by H. Reimann, Philadelphia, W. B. Saunders Company, 1938, page 91.

Artificial pneumothorax was once used as a therapeutic measure for lobar pneumonia and for a brief time in the 1930's was popularized by Blake. The subject is discussed in "Pneumonia," by R. Heffron, New York, the Commonwealth Fund, 1939, on pages 611, 749 and 769.

"PERMUTIT"

To the Editor:—Please give information or references to use of "permutit," said to be a chemical which removes salt from a normally ingested diet, making a salt-free or salt-poor diet unnecessary in cardiac and hepatic cases.

Willis P. Baker, M.D., Santa Ana, Calif.

ANSWER.—During the war a number of compounds were tried for their effectiveness in the desalination of sea water. Among the various substances studied were certain resins or ion exchange materials and zeolites, or "permutit." For example, a sodium or calcium resin in gastric juice would adsorb the hydrogen ion and give off sodium, whereas an acid resin in the intestine would adsorb sodium, magnesium, potassium and calcium and give off hydrogen ions. Zeolites or certain inorganic materials act analogously.

W. Dock (Tr. A. Am. Physicians 49:282, 1946) used a resin made by the American Cyanamid Company which in 2 ounce (56.7 Gm.) amounts would remove the sodium in 3 Gm. of sodium chloride. One generally thinks of "permutit" as being an inorganic material, but at a recent meeting of the American Chemical Society it was reported that "permutit Z" was used to adsorb sodium (Abstracts, 113th Meeting Am. Chem. Soc., Chicago, April 19-23, 1948, p. 2c). "Permutit Z" is actually an ion exchange resin made by the Permutit Company which adsorbs not only sodium, but also magnesium, potassium and calcium.

The use of the ion exchange resins orally for the absorption of sodium is now under laboratory investigation. Acid resins should not be used therapeutically now unless the physician is prepared to study the mineral balance of his patient.

SCLEROKERATOSIS

To the Editor:—A young matron, aged 24, has had, since the age of 8, four recurrences of tubercular scleritis and keratitis. Each attack has been prolonged in course and has been treated by rest and gradually increasing doses of old tuberculin. She has never had evidence of other tubercular lesion despite thorough examination and roentgenogram of the chest at each attack and occasional observation in the intervals. This patient has just had a recurrence for which the described treatment has been given. Has there been any recent development in the treatment of tubercular eye conditions which would improve on this regimen? Is streptomycin of any use in this condition?

W. F. MacDonald, M.D., Schenectady, N. Y.

ANSWER.—The local treatment for sclerokeratosis is atropine sulfate 1 per cent to 3 per cent, twice daily to keep the pupil fully dilated. Cases resistant to the usual treatment sometimes respond to beta rays or Grenz rays. The dosage of beta rays is a total of 175 to 200 per cent erythema dose given over four to six weeks in one course, which may be repeated. The dosage of Grenz rays is 452 roentgens filtered through 0.024 mm. of aluminum twice a week for five treatments. The systemic treatment for sclerosing keratitis is salicylic acid 20 grains (1.29 Gm.) every three hours for five doses. If the diagnosis of tuberculosis is made by subcutaneous injection of old tuberculin a course of therapeutic tuberculin may be given. Streptomycin has not been reported as used clinically. However, streptomycin could be used in 0.5 Gm. doses twice a day, and one should try to give a total dose of 65 Gm. if one believes that the patient would not experience damage to the vestibular branch of the eighth nerve.

ALOPECIA IN WOMEN

To the Editor:—A 58 year old married white woman began losing her hair about eighteen months ago. Thinning has been generalized, but most pronounced in the vertex and frontal regions. Loss of pubic or axillary hair has not occurred. About one year ago she noticed moderate growth of hair on the upper lip, legs and forearms. Menopause occurred at age 50. Her general health has always been good. History is essentially negative. Two brothers were prematurely bald in their late twenties. Examination reveals the following: The scalp is clean, almost shines. The hair is coarse and dry. Numerous broken hairs can be seen. The skin is of normal texture for one of her age. A noticeable but not prominent growth of hair occurs on the upper lip. The patient is about 15 pounds (6.8 Kg.) overweight. She is alert and appears to be emotionally well balanced. The blood pressure is 150 systolic and 88 diastolic; pulse rate 80; temperature 98.6 F. The Kahn reaction was negative. The red blood cell count was 3,900,000; the hemoglobin 80 per cent. Basal metabolic rate has not been obtained. At the present she is receiving thyroid, 1 grain (0.06 Gm.) daily. Suggestions for therapy and further investigation are requested. Is there rationale for use of pituitary extract in a case of this kind?
M.D., Texas.

To the Editor:—Is excessive loss of scalp hair in a 42 year old woman, without other menopausal symptoms, associated with an endocrine factor? Some loss of hair—beyond physiologic amount—has occurred for the past ten years, but lately this has become greatly accelerated. No dermatologic condition of the scalp exists. The hairs are thin and break off easily in ordinary combing. The frontal and occipital regions in particular have become devoid of much hair. No definite area of alopecia exists, but there is a general thinning of hair over the entire scalp. Associated excessive loss of hair or growth does not occur at present anywhere else on the body. There has been some hypertrichosis of the face in the past. 1. Can nervous or mental strain be an etiologic factor? 2. Would a past history of high cervical radiculitis with roentgen therapy (over eight years ago) account for excessive loss of hair now? 3. This condition is not familial in the patient's family. What is the prognosis for recession or progression? 4. How commonly do women under 50 have to use transformations because of excessive loss of hair not due to disease of the scalp? 5. Is stimulating scalp treatment of value?
M.D., California.

ANSWER.—Apparently both of these patients have male pattern baldness, which is relatively rare in women. Students of the subject generally agree that in the production of common baldness many factors play a role, particularly androgenic influences and heredity. According to Osborn's study, common baldness is inherited as a sex-limited trait dominant in men and recessive in women, and it is directly inherited from father or mother to son even though the mother herself is not bald. When the inheritance is duplex, baldness appears in women. Hamilton has pointed out that the lack of baldness among eunuchoid men, the subsequent development of baldness in these men after treatment with androgenic substances, and the presence of male pattern baldness in women with adrenal virilism or arrhenoblastoma are all evidence indicative of androgenic influence.

All women with male pattern baldness, therefore, should be examined for evidence of endocrine abnormalities, particularly of the adrenal glands. In the first patient, it would be well to determine the basal metabolic rate before administering more thyroid substance. Sufficient reason does not appear in this case to administer pituitary extract. In the second patient, it is unlikely that nervous strain is playing a role in the production of her baldness, nor would a history of cervical radiculitis treated with roentgen rays eight years previously be a factor. In general, the prognosis is decidedly guarded, for such baldness may rarely progress to the point where a transformation has to be worn. Treatment with stimulating measures is usually worth the effort expended: massage either with the fingers or an electric device; "hair tonics," i.e., scalp lotions containing a rubefacient, and suberythema doses of ultraviolet rays. For these 2 patients, it might also be well to institute therapy with estrogenic substance.

ALASKA ASTHMA

To the Editor:—What is the incidence of asthma in Alaska? Are people who go there from the Ohio area for example benefited or made worse?
P. C. Rond, M.D., Columbus, Ohio.

ANSWER.—Statistics on the incidence of asthma in Alaska are not available. The likelihood of benefit to an asthmatic person from Alaska climate is dependent primarily on the type of asthma. If the asthma is due to such seasonal allergens as ragweed pollen or mold the chances for relief are excellent. If city smoke and dust are known to be potent factors in the individual case, improvement in Alaska is likely. On the other hand, if the asthma is perennial or of the infectious type, or aggravated by damp or cold weather, the Alaskan climate may aggravate the condition. In many instances the factors involved are so indeterminate that only an actual trial residence can settle the issue.

PEPTIC ULCER

To the Editor:—Do ulcers of the stomach, or peptic ulcers, occur in absence of gastric hydrochloric acid? A patient was told by a consultant that he had an ulcer and anacidity, and dilute hydrochloric acid was prescribed.

A. B. Hooton, M.D., Olar, S. C.

ANSWER.—Assuming that a small ulcerative lesion of the stomach is actually present, as verified by the clinical history and roentgenologic examination, the absence of free hydrochloric acid, especially after stimulation with histamine, would make necessary the exclusion of carcinoma in particular, also gastric syphilis, tuberculosis or lymphogranulomatous lesion. With a stimulus like the Ewald meal or its modifications, the lack of free hydrochloric acid in the gastric contents is occasionally noted, even in the presence of an active benign ulcer, especially on single aspiration. Under the circumstances it would be inconsistent to prescribe hydrochloric acid, assuming the presence of a roentgenologically demonstrable gastric lesion.

SECRETORY OTITIS MEDIA

To the Editor:—A patient had recurrent attacks of serous otitis media for two years, and a fluid level would be seen behind the ear drum. This was treated, as the recurrence appeared, by paracentesis with a 20 or 22 gage needle and suction. After aspiration, the ear would remain free for three to four weeks, then the fluid would gradually accumulate. Finally roentgen examination of the mastoid showed mastoid involvement, and a simple mastoidectomy was performed. The cells were broken and filled with debris. The operation apparently was done completely and the area healed nicely except that there was a moderate amount of drainage of this serous material. It was kept open for a while and finally allowed to close. There was a prompt reappearance of the serous material behind the ear drum. Consultation has not helped, and we are thinking of making a permanent perforation of the ear drum in the hope that while this will not prevent the formation of the fluid it will at least allow it to drain whenever it forms. I would appreciate some help on this problem.

Kennard Yaffe, M.D., Baltimore.

ANSWER.—Serous otitis media, or as is more often called, secretory otitis media, is generally due to obstruction of the eustachian tube with resulting negative pressure in the middle ear cavity and accumulation of serous transudate. Removal of the obstruction to the eustachian tube may result in spontaneous resolution. If the fluid has been present for some time, a paracentesis of the tympanic membrane may be necessary to assure resolution. Where the condition exists without visible pathologic change at the mouth of the tube, it is frequently on an allergic basis. Eosinophils can be demonstrated in the serous fluid in such cases. Until the underlying allergy is discovered and removed, the condition tends to recur. The history, cutaneous tests and particularly the use of elimination diets should be employed to find the offending substances.

RECURRENT ERYSIPELAS

To the Editor:—What is the prevention of recurrent erysipelas of the right arm in a woman who has had nine attacks in five years following a right radical mastectomy? Moderate lymphedema occurs. Dermatomyositis is absent. Streptococcus vaccines, both stock and autogenous, have not been of value, nor has 70 per cent alcohol applied to the skin.

Milton Kissin, M.D., New York.

ANSWER.—The fact that erysipelas is noted for its tendency to recur would indicate that treatment aimed at inducing immunity is somewhat less than satisfactory. Several authors, however, report good results from the use of Streptococcus erysipelatis toxin and they stress the importance, too, of eradicating foci of streptococcus infections in sinuses, teeth and tonsils. Treatment with toxoid may be worth a trial in this case. In the past, foreign proteins, such as typhoid vaccine and milk, have had their advocates. If the patient should suffer another attack of erysipelas, it would be well to treat her with huge doses of antibiotics and for a longer period than is usual.

CATARACT

To the Editor:—I have opacities in both lenses with visual loss of about 50 per cent. What is the present status of operation of the soft lens?

M.D., California.

ANSWER.—Whenever the vision is decreased by the lens opacity sufficiently to interfere with the patient's daily life a surgical operation for removal of the opacity is justifiable. The amount of useful vision in a cataractous eye varies with the patient's work, mental attitude and temperament. If a decided handicap results with only a slight decrease in vision the operation is advisable.

It is unnecessary to wait until the cataract becomes more mature as was the previous custom.

EFFECTS OF SMOKING

To the Editor:—I have recently been told that my symptoms suggested an occlusive arterial disease in my feet and that a possibility of coronary insufficiency exists. My doctor advised that I stop smoking. I am aware that this is the usual advice, but I needed some scientific evidence to convince myself of the necessity of the giving up a lifelong pleasurable habit, and so tried to look up the subject. In five standard texts on the practice of medicine, the only reference to tobacco, smoking or nicotine was a short sentence stating that a toxic amblyopia results from tobacco. What is the effect of smoking cigarettes? If the practice is harmful, how does one treat withdrawal symptoms? Is the resulting nervousness less harmful than the practice of smoking, especially in coronary disease?

M.D., California.

ANSWER.—The effect of smoking cigarettes on the circulation of the lower extremities has been shown to be deleterious in a person who already has a deficient circulation. Cigarettes are especially bad, since they are generally inhaled. It has been shown that smoking reduces the amount of blood going to the feet by a considerable amount. Only one way to stop smoking is effective, and that is to stop it 100 per cent. The withdrawal symptoms are not harmful and should not effect coronary heart disease. Lampson reported some investigations on the effect of smoking on the lower extremities and showed a diminution in blood flow for several hours after smoking cigarettes. This was published in *THE JOURNAL* (104:1963, 1935). Maddock and Coller also reported peripheral vasoconstriction after smoking (*Ann. Surg.* 98:70, 1933). Little question exists that tobacco smoking, especially cigarettes, does produce a certain degree of vasoconstriction. There is such a large margin of safety in the normal person that this degree of vasoconstriction does not cause any serious effects. However, in a patient with a diminished arterial circulation any decrease in the amount of blood flow reaching the extremity, caused by even a slight degree of vasoconstriction, may be sufficient to produce serious effect. There is little if any evidence at hand that tobacco causes constriction of the coronary blood vessels. However, Theis and Freeland (*Ann. Surg.* 113:411, 1941) reported that smoking in patients with thromboangiitis obliterans caused a greater reduction in the oxygenation of the blood than in the normal person. This observation if true might indicate that it is also deleterious in patients with coronary disease. It would appear that the majority of evidence is that tobacco smoking is harmful for patients with peripheral vascular disease. The benefits derived from cessation of smoking far outweigh deleterious effects that might be produced by the withdrawal of smoking.

CRYPTORCHISM

To the Editor:—In the May 15, 1948 issue of *The Journal* is a query concerning a case of bilateral cryptorchism in a man of 21, with complete aspermia. The inquirer's question is whether hormone therapy is advisable or surgery is indicated.

In connection with your answer, "Unless the patient has some evidence of endocrine dysfunction, there is no indication for any hormonal therapy and a bilateral orchiopexy is indicated," I want to call your attention to the generally accepted routine procedure in cases of cryptorchism, which is to try to cause the testicles to descend by endocrine therapy before resorting to surgery, i.e., orchiopexy, which is acceptable only in mechanical obstacle to descent. Since in this case, the testicles are retained in the abdominal cavity, the surgical intervention (in addition to the operative risk) may prove harmful to the glands, particularly if and when a short pedicle will have to be elongated, with a possibility of complete and permanent atrophy of the glands.

P. M. F. Bishop (*Guy's Hosp. Rep.* 94:12-74, 1945), considers it well to administer a preoperative course of endocrine therapy, not only to insure development of the testis, but also to assist in lengthening the cord, if necessary. I think it is indicated in the inquirer's case because of such evidences of hypogonadism as complete azoospermia and considerable overweight (Froehlich's type of hypogonadism).

S. I. Movitt, M.D., Los Angeles.

DEXEDRINE

To the Editor:—The claim of Dr. G. Raymond Johnson of Ottumwa, Iowa, in *Queries and Minor Notes*, *The Journal*, June 19, page 756, that "dexedrine" produced diabetes in one patient is invalid, in view of your comment that no evidence exists which supports this opinion. We question your statement that diabetic symptoms may be aggravated by the drug and that diabetes is a contraindication to its use.

In a study just completed, we found no instance of aggravation of diabetes by "dexedrine" in a series of 55 obese diabetic patients. In fact, 31 of these patients presented improvement as measured by the glucose tolerance test or by reduction of insulin requirement. The improvement noted in carbohydrate tolerance was probably the result of dietary restrictions and weight reduction. Clinically, "dexedrine" appears to have no direct effect on the diabetes or its course.

Henry Dolger, M.D.,
Kermit E. Osserman, M.D., New York.

EARLY DIAGNOSIS OF CANCER BY STUDY OF EXFOLIATED CELLS

MAURICE FREMONT-SMITH, M.D.

RUTH M. GRAHAM, B.S.

and

JOE V. MEIGS, M.D.

Boston

Until the cause or causes of cancer are discovered, the only way cancer can be controlled is by early diagnosis and the consequent eradication of the malignant lesion at its inception. In the majority of cancers early diagnosis is not now possible. How is the physician to suspect, much less perform a biopsy of, a symptomless cancer of the stomach or lung which cannot be visualized? How shall one suspect cancer of the cervix in the presence of a grossly normal organ and before abnormal bleeding? In many parts of the body malignant lesions present for months or even years may be attended by their first clinical symptom only after invasion or metastasis has taken place.

Because of its recognized value and in order to check its misuse we propose to outline the present status of the cytologic method of cancer diagnosis. We believe that in certain regions of the body an earlier diagnosis of cancer can be made through proper use of this method than can be achieved by any other means. Particularly is this true of cancer of the uterus and the lung. There is reason to hope that detection of early cancer of the stomach and the urinary tract may also become practicable by the use of the cytologic technic.

After six years of extensive experience with the study of exfoliated cells at the Massachusetts General Hospital, it is our conviction that the cytologic method has become an essential procedure for the early diagnosis of many types of malignant disease. In its use, however, as in any diagnostic maneuver, judgment must be used, and those making the diagnosis must be completely familiar with the technic. Forty years ago William Osler wrote: "To be exploited prematurely in practice is the common fate of all new scientific facts. Not content to wait for full knowledge, men hastily draw conclusions from imperfect data." Exploitation of the diagnostic method to be discussed has already occurred.¹ Reliance on a diagnosis, for or

against cancer, submitted by an inexperienced "cytologist" constitutes malpractice as surely as does the performance of a major operation by an inadequately equipped surgeon. The misuse and exploitation of this method by untrained persons cannot be tolerated.

The story of cytologic diagnosis begins over one hundred years ago when Pouchet² first examined unstained preparations of vaginal fluid in an attempt to analyze the normal sexual cycle. Seventy years later, in 1917, Stockard and Papanicolaou,³ seeking a way of studying the consecutive stages of estrus in the guinea pig, reexamined the vaginal secretion. They developed the technic of rapid fixation and staining which made possible for the first time accurate cytologic observation of the vaginal fluid. In the rodent, the study of the vaginal secretion proved unexpectedly rewarding. A specific cytologic picture was seen for each successive phase of the estrous cycle, thus making accurate identification of each phase possible. In human beings, however, results of vaginal smears have proved disappointing. Although a vaginal epithelial rhythm is present in women, the clearcut sequence of cytologic events observed during the estrous cycle in the guinea pig is not observed. Specific changes dependent on ovulation are not seen. In the normal woman, the changes visible in the vaginal secretion following ovulation are due not to the specific action of progesterone but to the decrease in estrogen secretion which follows follicle rupture. Similar changes occur whenever estrogen is suddenly withheld from a previously estrogen-treated castrate female subject. Papanicolaou⁴ said, "The vaginal smear offers only indirect evidence as to ovulation and the time of its occurrence." Quantitative changes in the amount of estrogen, however, may be estimated by the vaginal smear, and the test is, therefore, useful in determining the functional activity of the ovaries (or of extraovarian sources of estrogen) and in judging the adequacy of estrogen therapy in postmenopausal women.

In 1923 Papanicolaou became impressed by the abnormal features of certain cells observed in the vaginal secretion of women with cancer of the uterus and suggested that the vaginal smear should be useful in the diagnosis of malignant uterine disease. His first

publication⁵ on this subject appeared in 1928 and a second⁶ in 1933. Little interest, however, was aroused by his early observations. Six years devoted to a study of other aspects of vaginal cytology passed before Papanicolaou again⁷ in 1941 reiterated his conviction that uterine cancer could be accurately diagnosed by vaginal smear. This publication focused our attention on the problem and we⁸ were the first to confirm Papanicolaou's results. Evaluation of the method is still in progress and its applicability to the diagnosis of cancer in other organs besides the uterus is under active investigation.

The biopsy remains the final method of establishing a diagnosis of cancer; until recent years it has been the only means by which a diagnosis of cancer could be made. Any alternative method to be acceptable must be theoretically sound, statistically reliable and superior, at least in certain respects, to biopsy. Evidence will be presented that the cytologic method fulfils these requirements.

RATIONALE

Diagnosis by the cytologic method depends on the fact that malignant tumors on any free surface desquamate tumor cells into the surrounding medium. It is known that there exists a continuous exfoliation of cells from every epithelial surface of the body. Thus the vaginal secretion, the sputum and the urine normally contain cells desquamated from the corresponding epithelial surfaces. There is evidence⁹ that tumor cells may desquamate even more rapidly than normal cells and that such malignant cells can be accurately identified. If the presence of tumor cells in any body fluid is correctly established, such cells must have taken origin from an area of tumor proximate to or in contact with the fluid examined.

Criteria have been established¹⁰ for the identification of malignant cells and their differentiation from the many types of normal cells exfoliated into the body fluids. These criteria are based on recognizable morphologic changes in the nucleus and cytoplasm of cells found in the body fluids of patients with malignant disease, and not found in the absence of malignant lesions. Direct smears from malignant tumors obtained at operation show cells identical with those present in the body fluid of the person bearing the tumor.^{8a}

That fundamental alterations in structure accompany the transition of normal into malignant cells is suggested by observations of Firor and Gey.¹¹ These investigators studied in vitro cultures of normal rats' fibroblasts. On three occasions some of the normal fibroblasts became permanently altered; inoculation of young

healthy rats with the altered cells was followed by the development of sarcomas at the point of inoculation.

The authors said:

At first the newly altered cells showed nuclei that were slightly larger than those of the cells of origin. Later the nuclei became irregular in outline, very granular, and in stained preparations, the altered nuclei were hyperchromatic. . . . The changes just described were shown to be coincident with the development of malignant characteristics, for when colonies of altered and unaltered cells were inoculated into the rats, the former produced sarcoma at the sites of inoculations, the latter never did. It is significant that the cellular changes accompanying malignant transformation in rats' fibroblasts, namely, enlargement of the nucleus, enlargement of nuclear granules and nuclear hyperchromatism in stained specimens, are identical with the morphologic alterations commonly observed in cells desquamated from human cancer. The differentiation of cancer cells from normal cells in body fluids depends to a large degree on these very criteria.

COLLECTION OF MATERIAL

The collection of material for examination is simple. In the case of vaginal smears, a pipet 6 inches (15 cm.) long with capillary opening and capped by a rubber suction bulb is introduced into the posterior vaginal fornix; the bulb is released and aspirated fluid is blown on a previously marked glass slide, which is immediately dropped into a fixative of equal parts of 95 per cent alcohol and ether. Neither douching nor pelvic examination should precede the collection of the specimen.

Sputum is spread thinly on glass slides and similarly fixed. Search is made to obtain blood-flecked bits of sputum for examination.

For examination of the urine an entire fresh morning specimen is centrifuged and the sediment spread on three slides which have been previously covered with egg albumin. The slides are fixed in alcohol and ether. Ten cubic centimeters of 40 per cent formaldehyde may be added to the urine if immediate centrifuging is not possible.

For the cytologic study of gastric contents our laboratory now examines two specimens. The first is the fasting gastric content, secured through a Levin tube with additional openings cut in its terminal 8 inches (20 cm.). The tube is passed in the usual manner and the patient allowed to drink water during its passage. After the stomach is emptied, 100 cc. of isotonic solution of sodium chloride is injected and allowed to come in contact with all surfaces of the organ by turning the patient on either side and face downward and by having him walk about. The fluid is forcibly aspirated and reinjected several times during this period. Both specimens are centrifuged and the sediment smeared thinly on glass slides and fixed and stained in the usual way.

All preparations are stained by Papanicolaou's method, details of which may be found in previous publications.¹²

While the technic of preparation is simple, the ability to make accurate diagnoses by this method is difficult to acquire, obtainable only by months of intensive training and perfected only through constant use. A physician or laboratory technician examining a few preparations a month cannot obtain competence in this diagnostic technic. The differentiation of cancer cells from normal cells, be they in tissue preparations or smears, belongs within the province of the pathologist. If diagnosis by exfoliative cytology is as valuable as many of us believe, it must become the responsibility of the pathologist to acquire the same skill in the interpretation of smears that he now possesses in the diagnosis of tissue sections.

CANCER OF THE UTERUS

Of the two types of uterine cancer, carcinoma of the cervix presents by far the more serious problem. Found in women in their forties and early fifties, five times as often as is endometrial cancer, cervical carcinoma develops more insidiously and metastasizes earlier. Its occurrence, moreover, proves a calamity not only for the patient but for her entire family, as the majority of the victims are women in the prime of life, often the mothers of young children.

Although the cervix is readily visualized and cancer of this organ is believed to give early evidence of its presence either by abnormal bleeding or by the development of a visible lesion, cervical cancer is often still diagnosed only in an advanced stage. Recently it has been recognized that cancer of the cervix may exist for months or years before the appearance of either symptom or sign. The average age at which evidence of cervical cancer appears is known to be 48 years. TeLinde and Galvin¹³ and Pund and Auerbach¹⁴ found 36 years to be the average age for the appearance of carcinoma *in situ*. Younge¹⁵ found carcinoma *in situ* in 135 women, whose average age was 38 years. Thus cancer of the cervix must occur on the average ten years before clinical evidence of its presence.

When abnormal bleeding does appear usually in the late forties, such bleeding is too commonly ascribed by both patient and physician to menopausal irregularity, and examination, therefore, is postponed. At the time bleeding first appears, however, the situation is often already grave. Maliphant,^{15a} studying 837 cases of cervical cancer, observed the disease to be in an advanced stage in 60 per cent of women seen six months after the onset of spotting and advanced disease in 50 per cent of those examined only three months after the onset of spotting. Todd¹⁶ has estimated that from onset of bleeding chances of cure decrease 3 per cent per week. The average delay from the onset of abnormal bleeding to the institution of treatment is seven and a half months.¹⁷ Thus lives are lost because the diagnosis of cancer may not even be suspected until the disease is beyond hope of cure. While routine biopsy, if correctly performed, will reveal most cases of early cancer, biopsy is a hospital procedure except in the office of the gynecologic specialist. It is, moreover, manifestly impracticable to obtain repeated biopsy specimens from symptomless women. The vaginal smear, on the other hand, is technically simple to procure. If sufficiently accurate, the vaginal smear should offer a means of detecting cervical cancer earlier than can be practically accomplished in any other way.

In 1947 statistics concerning approximately 5,000 patients examined by vaginal smear were collected by

Gates and Warren.¹⁸ Estimates of accuracy of the vaginal smear varied from 96 to 99 per cent. However, the authors correctly remarked that by the inclusion in any series of an increasing preponderance of negative results, the apparent accuracy of the test can be made to approach 100 per cent.

Since Gates' and Warren's compilation, Isbell, Jewett, Allan and Hertig¹⁹ have reported 1,045 cases, including 58 proved cases of cancer of the uterus, in which again the over-all accuracy of the vaginal smear was 98.5 per cent. Of 40 cases of carcinoma of the cervix, positive smears were obtained in 39. Of 18 cases of malignant disease of the fundus, however, smears were positive in 15, and negative in 3.

Scheffey, Rakoff and Hoffman²⁰ reported, in 1948, 63 proved cases of cancer in 500 consecutive gynecologic admissions. The over-all accuracy of the vaginal smear method was 95 per cent. However, positive smears were obtained in only 70 per cent of cervical and 67 per cent of endometrial cancers.

Our experience in the Vincent Memorial Laboratory in the years 1942 to 1947 is based on the examination of vaginal smears from 5,621 women, of whom 492 had uterine cancer. All figures are based on the initial smear report. This series includes 113 cases of endometrial carcinoma, in 83 of which diagnosis was made by smear, an error of 26.5 per cent; and 354 cases of cervical carcinoma, in 317 of which diagnosis was made by smear, an error of 10.5 per cent. There have been 69 cases in which a positive diagnosis made by smear was not confirmed at pathologic examination. This represents a "false positive" diagnostic error of 1.3 per cent. It is evident that if cases with proved cancer only are considered, the smear fails to detect the malignant disease in about 20 per cent of endometrial and 10 per cent of cervical carcinoma. As will later be seen, biopsy likewise misses some 10 per cent of cervical cancers.

Of particular interest is a group of preinvasive carcinomas of the cervix studied at the Vincent Memorial Laboratory both by vaginal smear and by biopsy. Sixteen cases have already been reported.²¹ The number has now been increased to a total of 30 cases.

Thirteen of these 30 women (or nearly 50 per cent) presented no gynecologic symptoms. The initial vaginal smear was positive in 23. Biopsies were performed for 27 of the same patients. The results of the initial biopsy were positive in 13, questionable in 4 and negative in 8. In 2 cases no tissue was obtained. In 2 cases in which cancer was missed by vaginal smear, the result of the initial biopsy was correctly positive. Thus in a series of 30 cases, the initial vaginal smear proved significantly more accurate than did the initial biopsy in detecting preinvasive cancer of the cervix.

A comparison of the accuracy of the vaginal smear with that of the biopsy in 181 cases of proved epidermoid carcinoma of the cervix was made by Graham, Sturgis and McGraw.²² In this series the result of

the initial biopsy was correctly positive in 90 per cent; the initial vaginal smear was correct in 91 per cent. The two methods combined achieved a diagnostic accuracy of 99 per cent. In this connection it seems appropriate to quote the words of two conservative investigators. Isbell and Hertig said: "The [vaginal smear] method has proved unexpectedly valuable in the study of early carcinoma and carcinoma-in-situ as well as in the diagnosis of more advanced cases." Gates and Warren commented: "Overemphasis on the statistical accuracy seems to put the stress in the wrong place . . . the thing that matters is whether the use of the method will discover cancer and initiate treatment earlier than would otherwise be done."

Annual deaths in the United States from carcinoma of the cervix approach 17,000. All, or a great majority, of these women could be saved were the cancer discovered sufficiently early. In how many women will early cancer of the cervix be found? Estimates of the incidence of carcinoma *in situ* of the cervix vary from 0.29 per cent (Gates and Warren¹⁸) to 3.7 per cent (Pund and Auerbach¹⁹). Younge¹⁵ examined 955 routine cervical biopsy specimens taken in the Out-patient Department of the Free Hospital for Women and found 11 instances of carcinoma *in situ* (1.15 per cent).

The majority of women with preinvasive cancer have no symptoms, and the cervix gives little indication of disease. Of Pund's and Auerbach's 47 patients, only 1 out of 4 had abnormal bleeding, and the presence of cancer was not recognized from the gross appearance of the cervix in a single case. Of Younge's 135 patients, 46 per cent were symptomless, 80 per cent showed what was described as an "innocent erosion" of the cervix, 7 per cent presented frankly normal cervixes and in only 6 per cent was the cervix considered "suspicious." In 2 of Younge's patients, each with a diagnosis from biopsy of carcinoma *in situ*, invasive carcinoma developed after intervals of three and a half years and one year, respectively. The way to prevent the development of uncontrollable advanced cervical cancer is by discovery and eradication of the early lesion before invasion or metastasis has occurred. It is evident that detection of early unsuspected cervical cancer should be possible by vaginal smear.

Few reports of screening by vaginal smear have appeared. Pund and his collaborators²³ detected 7 cases of preinvasive carcinoma by routine endocervical smears. The total number of women examined was not given. Kraushaar²⁴ took a single vaginal smear from all women over the age of 30 admitted to the Hospital of the University of Iowa since January 1947; 1,931 women were so examined. Sixty-two positive smears were obtained, 52 of which were confirmed by tissue pathologic examination and 2 by clinical examination. Negative results of biopsies were obtained in 3 cases with positive smears. In 12 cases the smear failed to disclose uterine carcinoma later discovered in tissue section. In reference to a larger series, of about 4,000 cases, Kraushaar wrote: "We have detected by smears and proven by tissue sections

12 cases of carcinoma of the cervix, either as carcinoma-in-situ or early epidermoid carcinoma; in which the cervix appeared to be normal clinically." Palermo,²⁵ screening 827 gynecologic patients, discovered three unsuspected cervical carcinomas. Scheffey and Rakoff²⁶ found only 7 cases of uterine carcinoma in a screening of approximately 5,000 cases, including many young women.

We²⁶ have published the results of screening 200 unselected office patients by vaginal smear. The series now totals 358 women, each examined by a single vaginal smear. These women came to the office of an internist for general physical examination. Only 25 complained of either bleeding or abnormal discharge. Six positive smears were obtained, 5 of which were confirmed by pathologic examination—carcinoma *in situ* of the cervix in 4 and endometrial cancer in 1 case. Of the 4 patients with cervical cancer, no gynecologic symptoms were present in 2 and the cervix was normal to visualization in all. This small series tends to confirm previous evidence that about 1 woman in every hundred bears in her cervix an early malignant lesion, often invisible and symptomless. The discovery of even one preinvasive cancer justifies the examination of many smears. Whether screening by smear as a public health measure will become economically-practicable is a question that cannot now be answered.

M. B., a woman of 43, came to my office complaining of diarrhea and arthritis. There had been no bleeding or discharge. Routine examination disclosed a lacerated cervix. Vaginal smears were twice positive for cancer. A biopsy showed carcinoma *in situ*. A Wertheim hysterectomy was performed by Dr. Meigs. According to the pathologic report the cervix appeared normal grossly. Microscopic examination disclosed squamous cell carcinoma *in situ*.

D. C., age 42, complained of a mass in the breast. There was no vaginal bleeding or discharge. The cervix appeared normal. A vaginal smear was doubtful and a repeat smear positive. Results of biopsy were positive for cancer. A total hysterectomy was performed. No gross lesion was visible, but microscopic examination showed squamous cell carcinoma *in situ*.

A. S. had no symptoms. A routine vaginal smear was positive. A week later a second smear was positive and biopsy revealed epidermoid carcinoma *in situ*. A total hysterectomy was performed by Dr. Meigs. Pathologic examination revealed epidermoid carcinoma *in situ*.

Without a routine vaginal smear these and similar cases of early cervical cancer would not have been discovered. How many women in their early forties with neither bleeding nor discharge and with a cervix normal to inspection would be sent to a gynecologist for biopsy, and with what likelihood that a biopsy specimen, if taken, would contain the area bearing the cancer?

At this point a word should be said as to the significance of vaginal smear reports. A negative smear does not exclude the possibility of cancer. As has been stated, the initial smear will miss about 1 case of cervical carcinoma in 10. A report of positive results indicates biopsy or curettage; it does not indicate operation. An occasional false positive result is inevitable. Biopsy confirmation must be obtained in every case before operation is advised.

CARCINOMA OF THE LUNG

In carcinoma of the bronchus, early diagnosis is rarely made. Early in the disease a definitive diagnosis by roentgenogram or bronchoscope is usually impossible. Herbut and Clerf²⁷ stated that by the time cancer is positively diagnosed by bronchoscopic examination or by biopsy, "... the lesion has too often infiltrated such vital structures that surgical extirpation is impossible."

Attempts to diagnose bronchogenic carcinoma by examination of sputum or bronchial secretion have been increasingly successful.

Dudgeon²⁸ (1937) found evidences of carcinoma from the examination of sputum smears in 77 per cent of 56 cases. Gowar²⁹ (1943) reported the observation of tumor cells in 64 per cent of 93 cases. Wandall³⁰ (1944) diagnosed the disease correctly by sputum examination in 84 per cent of 100 cases of bronchogenic carcinoma.

Herbut and Clerf³¹ reported the detection of cancer cells in the bronchial secretion of 25 (92.5 per cent) of 27 consecutive cases with carcinoma of the bronchus; the disease in 12 cases with completely negative results of bronchoscopic examination was correctly diagnosed by smear. These authors stated that by cytologic study the disease in an additional 20 to 25 per cent of cases, with lesions beyond bronchoscopic vision can be diagnosed; and stressed that this percentage represents those cases in which the growth is most amenable to complete surgical removal. To date a total of 800 patients, including 180 with proved bronchial carcinoma, have been examined by Herbut.³² Cancer cells were observed in bronchial secretion of 161, or 89 per cent. By contrast the results of biopsy were positive in only 71 cases, or 39 per cent. Results of examination of secretions were positive and results of bronchoscopy completely negative in 51, or 29 per cent.

McKay and his co-workers³³ studied smears of secretion obtained in 170 bronchoscopic examinations. Of the 54 cases in which bronchogenic carcinomas were encountered, tumor cells were observed in 40 (74 per cent). Three false positive diagnoses were made. In 14 cases of bronchogenic carcinoma (25 per cent), results of bronchoscopy were negative and the smear was positive. Two further cases were reported with peripheral tumors not visualized at bronchoscopy. In both cases the smear was positive for tumor cells. Woolner,³⁴ examining bronchial secretion or sputum from 2,200 patients, obtained 200 positive smears. Only

4 of the 200 smears were proved to be false positive. Negative smears were obtained in about 10 per cent of cases of bronchial carcinoma.³⁵

Diagnoses based on examination of sputum are still regarded with skepticism by the clinical services, although in the Vincent Memorial Laboratory during the past year, not one false positive diagnosis based on examination of sputum has been made.

A 44 year old man complaining of cough of ten days' duration had dullness and bronchial breath sounds over the upper lobe of the right lung. Roentgenograms were suggestive of tuberculosis. Results of three sputum examinations were positive for cancer. On rounds "no one was convinced of the likelihood of tumor." At autopsy carcinoma of the bronchus and abscess of the upper lobe of the right lung were present.

A. G., a man of 63, complained of cough for a period of seven months. The diagnosis based on roentgenologic observations was pulmonary abscess. Cytologic examination of the sputum showed cells consistent with squamous cell carcinoma. Biopsy of a cervical gland, however, showed malignant lymphoma. Bronchoscopy revealed obstruction of the lower part of the right bronchus. Biopsy of material obtained at bronchoscopic examination revealed squamous cell carcinoma.

After the biopsy of the cervical gland, it was natural to assume that the pulmonary lesion represented infiltration by lymphomatous tissue. The smear, however, correctly indicated a second diagnosis, totally unexpected both by the roentgenologist and the clinician.

CANCER OF THE URINARY TRACT

Cancer of the kidney and bladder, even if early, is usually detectable by the classic methods of investigation. Nevertheless, cytologic examination occasionally reveals a malignant process overlooked at endoscopy.

A man of 78 complained of prostatitis and cystitis of ten years' duration. Cytologic examination of the urine sediment showed cancer cells in five smears over a twelve month period, during which time results of cystoscopy were twice negative. In January 1948, a tiny papilloma was seen in the base of the bladder on the left side, biopsy of which showed carcinoma grade IIIB.

I. M., a 60 year old man, complained of hematuria. Biopsy showed chronic and acute cystitis. Clinical diagnosis was benign prostatic hypertrophy. Results of cystoscopy were negative. Urine smears were positive for cancer. Three months later a second biopsy showed carcinoma. A cystectomy was performed.

Statistically, in comparison with examination of other body fluids, examination of the urine has been in our hands the least satisfactory. We have, however, been able to diagnose correctly 71 per cent of bladder carcinomas. Cancer of the kidney has been diagnosed in only 50 per cent of a small series and cancer of the prostate in only 42 per cent. In the urine, moreover, our false positive results have averaged 1 in 10, a figure higher than that occurring in the examination of any other body fluid.

Although the statistical accuracy in examination of urine sediments is not high, we have in a series of 225 cases discovered by this method 3 completely unsuspected cases of cancer, 1 of the kidney and 2 of the bladder.

According to Young³⁶ in only 1 in 5 cases is prostatic cancer diagnosed in a stage suitable for radical prostatectomy. Herbut³⁷ examined the prostatic secre-

tion obtained from 450 patients, 54 of whom had prostatic cancer. Cancer cells were correctly recognized in 39 instances, or 85 per cent. It is evident that in examination of prostatic fluid, as in the examination of bronchial and gastric aspirates, the percentage of correct diagnoses by the cytologic method varies directly with the interest and capability of the physician who collects the specimen. For cytologic diagnosis to be effective, the first requisite is that cancer cells be placed on a slide; the second is the recognition of cancer cells in the stained specimen. In cytologic diagnosis, proper collection of the specimen is as important as skill in interpretation.

GASTRIC CANCER

Because, until moderately advanced, cancer of the stomach usually presents no symptoms, discovery of gastric carcinoma in an early stage is rare. Despite the improvements in surgical technic during the last twenty years, little advantage has accrued to the patient with cancer of the stomach. Eighteen years ago 5 of every 100 patients with gastric cancer entering the Massachusetts General Hospital obtained five year cures. A decade later (1940) 7 of every 100 obtained a five year cure.³⁸ It is still often impossible to decide on roentgenographic evidence whether a given gastric lesion is malignant or not. At the Massachusetts General Hospital during the years 1931-1940, 14 per cent of gastric ulcers clinically (and roentgenologically) considered benign were observed to be malignant, and, conversely, 17 per cent believed to be malignant proved to be benign. The surgeon with the stomach in his hand often cannot determine whether cancer is present or not. It is, therefore, not surprising that in this disease late diagnosis is the rule rather than the exception.

Papanicolaou³⁹ in 1946 reported the recognition of cancer cells in gastric fluid. The following year Papanicolaou and Cooper⁴⁰ published a report on 137 cases, in 27 of which there was gastric cancer. Of the 27, results of cytologic examination were positive in 10, suspicious in 7 and negative in 10. Of smears from 110 patients without cancer, those of only 9 were called suspicious and none positive.

In the Vincent Memorial Laboratory we have studied sediments of gastric fluid from 193 patients. Of 65 patients with gastric carcinoma, positive smears were obtained in 35 (54 per cent). Of 128 patients without cancer, smears were mistakenly reported positive in 3.

While statistically these results are not satisfactory, an individual case not infrequently emphasizes the value of the test in the recognition of gastric cancer and suggests that with improved technic a larger proportion of positive results might be obtained.⁴¹

S. B., a man of 57, complained of dysphagia of six months' duration. A roentgenogram showed spasm of the esophagus; a

second roentgenogram showed no abnormalities. Gastroscopy revealed esophagitis, and a biopsy showed chronic inflammation. Cytologic examination of gastric contents revealed a malignant condition. A repeat gastroscopy showed spasm of the esophagus, and a malignant condition was suspected. At operation extensive cancer of the stomach was observed. Pathologic examination revealed signet ring carcinoma.

A. L., a woman aged 41, complained of regurgitation of nine years' duration and of epigastric pain of four years' duration. A roentgenogram in 1935 had shown a gastric ulcer. Roentgenograms ten years later, in 1945, indicated gastritis. Results of gastroscopy were negative. In 1947 gastroscopy revealed gastritis. One roentgenogram suggested benign polyposis and a second, early in 1948, gastritis. Smears of the gastric fluid were positive for cancer. At operation the surgeon observed evidence indicating gastritis only. Pathologic examination showed adenocarcinoma involving almost the entire mucosa of the specimen.

The next case is an example of the difficulty in recognizing cancer even though the stomach lies in the surgeon's hand.

E. C., 56 years old, suffered for six weeks with pain in the left upper quadrant of the abdomen. Roentgenograms indicated gastric neoplasm. Results of cytologic examination were positive. At operation Dr. Arthur Allen felt a soft movable tumor within the stomach; he expressed the belief that it represented a benign polyp. Only a limited subtotal gastrectomy was performed, and grossly the tumor appeared to be benign. The diagnosis based on pathologic examination was adenocarcinoma with metastasis to regional lymph nodes.

As previously stated, our results in the diagnosis of gastric cancer are so far not statistically satisfactory. However, Graham and Ulfelder from our laboratory⁴² have reported the correct diagnosis by smear in 5 cases of resectable gastric cancer, and in 2 extremely early cases of gastric cancer. In a small study group, to be reported later, changes in technic of collection of the gastric fluid have already resulted in a much higher proportion of positive smears. If a majority of early cases are found to be diagnosable by smear, the value of the cytologic method in the control of carcinoma of the stomach will be incontestable.

SUMMARY

The rationale, technic and accuracy of the cytologic method in the diagnosis of cancer is reviewed. It is shown that invisible lesions (cervix), noninvasive lesions (cervix) and tumors inaccessible for visualization or biopsy (lung, prostate) can be diagnosed by a study of exfoliated cells with an accuracy comparable to that of biopsy.

The likelihood of cancer in a patient with a positive smear is so high that this observation cannot be disregarded. A positive smear demands that every possible effort be made to establish the diagnosis. Radical therapy is justified, however, only if confirmatory evidence is obtained. A negative smear should never outweigh other evidence in favor of malignant disease.

While examination of fixed tissue sections remains the final criterion of malignant disease, evidence is presented that in the lung and cervix, and possibly in the stomach and prostate, cancer may be detected earlier by cytologic examination than is possible by any other means.

DIGITOXIN

Its Evaluation for Initial Digitalization of the Patient with Congestive Heart Failure

ARTHUR C. DeGRAFF, M.D.
ROBERT C. BATTERMAN, M.D.

and

O. ALAN ROSE, M.D.
New York

Several reports¹ have recently appeared concerning the value of digitoxin for the treatment of patients with congestive heart failure. It has been demonstrated^{1a} that the cat unit potency of digitoxin has no clinical relationship to that of digitalis leaf. It is essential, therefore, that extensive clinical studies be done to establish the proper dosage and the best methods of administration. Furthermore, since many glycosides are becoming available for clinical use, all should be thoroughly studied before any final decision is made concerning the selection of any particular glycoside as the one of choice. As part of our program, now in progress, for the evaluation of cardiac glycosides, digitoxin has been studied in several ways. Its use for the maintenance of the digitalized state in ambulatory patients has already been reported.² The purpose of the present report is to submit our experiences with digitoxin for the initial digitalization of the patient with congestive heart failure.

METHOD OF STUDY

Groups of patients with varying degrees of chronic congestive heart failure³ were given digitoxin⁴ according to one of the following oral methods: (1) a modified Eggleston method⁵ consisting of multiple doses, (2) a small daily undivided dose and (3) a single large dose as advocated by Gold and his co-workers.^{1cd} All patients were hospitalized and without exception were unselected except for the exclusion of patients with complications such as myocardial infarction, pulmonary disease and glomerulonephritis. None were moribund or considered too ill to be followed adequately after digitalization. With few exceptions, the patients had never previously been given any digitalis preparation, and the few exceptions had not received any for at least three weeks prior to digitalization. The fact that the majority of the patients were digitalized for the first time is considered to be important, since it has been our experience that many patients are more responsive to subsequent digitalizations. If a digitalis preparation is given again within a few weeks, the

patient who is being redigitalized may require a smaller dose to produce an adequate therapeutic response. All patients were at complete bed rest from the time of entering the hospital until the cardiac status allowed ambulatory care.

Before digitalization the maximum effect of the usual supportive measures was evaluated in each case. The duration of the control period varied from patient to patient depending on the severity of the heart disease and need for digitalization. Unless the patient's condition did not permit, the patient was observed usually for four to five days, and in some cases as long as two weeks before digitoxin was administered. None of the patients received any mercurial diuretic prior to digitalization. In general, the patients were observed according to the regimen established in previous studies.⁶

DIGITALIZATION BY THE MULTIPLE DOSE METHOD

Thirty-seven patients were given digitoxin according to a multiple dose schedule; i.e., they received an initial large dose, and subsequently at six hour intervals a smaller dose was administered until a definitely sustained therapeutic effect occurred or toxicity was noted. It should be made clear that the usual treatment of a patient with congestive heart failure does not require administration of digitoxin or any digitalis preparation to the point of toxicity. Once a sustained therapeutic effect is achieved a maintenance dose is advocated. However, in order to determine the therapeutic range, all patients were given digitoxin to the point of toxicity, the drug's administration being stopped at the first sign or symptom of its occurrence. The initial dose varied between 0.4 and 1.6 mg., with the greatest number of patients receiving 0.6 mg. Subsequent doses varied between 0.2 and 0.4 mg., with the greatest number of patients receiving 0.3 mg.

The therapeutic dose was ascertained in 27 of the patients and ranged between 0.9 and 4.8 mg., averaging 2.2 mg. In the other 10 patients, the therapeutic dose could not be established either because the minimal degree of congestive heart failure did not allow clearcut clinical evidence of improvement or because it was overshadowed by toxic manifestations. Most of the patients had initiation of improvement within twenty-four hours, but a satisfactory therapeutic effect was not achieved until at least forty-eight hours of digitalization. For each patient there was an optimum therapeutic dose which varied greatly from patient to patient. The size of the initial and subsequent doses did not seem to be material as long as the patient received sufficient digitoxin to be fully digitalized in the period of twenty-four to forty-eight hours. The best dosage scheme was found to be an initial dose of 0.6 mg. and then 0.3 mg. every six hours until the desired therapeutic effect was obtained.

The toxic dose ranged between 1.5 and 9.3 mg. (average 4.1 mg.). The type of toxicity was in no way different from that usually seen with the whole leaf of Digitalis purpurea. Anorexia, nausea and vomiting were commonly the earliest symptoms, but there was no way of predicting which patient would experience the more serious forms of toxicity such as abnormal rhythms and heart block, either concomitant with the mild symptoms or independently. This did not differ in any

respect from the toxicity noted with any digitalis preparation. However, the striking observation was the persistence of toxicity. In several patients toxicity persisted for many days, although the mild toxic symptoms usually subsided within forty-eight to seventy-two hours.

SLOW DIGITALIZATION WITH DAILY SINGLE DOSES

Twelve patients who were not acutely ill, so that slow digitalization could be followed without fear of jeopardizing the patient's welfare, were included in this group. The daily dose in all but 2 instances was 0.4 mg. This dose was selected because studies in the ambulatory patient² indicated that it is the minimal dose which would allow sufficient cumulation for relatively rapid therapeutic response and yet would be sufficiently high to result eventually in minimal toxicity. Digitalization was achieved in 9 of the 12 patients. A therapeutic response was not discernible in 3 patients, 2 of whom had only a questionable amount of congestive heart failure. The desired therapeutic response was noted in three to six days and required from 0.9 to 2.4 mg. (average 1.7 mg.). This dose is slightly lower than that noted for the multiple dose method, but the two groups are not comparable in terms of severity of congestive heart failure. Since the patients in this group were definitely in less congestive heart failure it is probable that they would require a smaller dose. That this is the most likely explanation can be reasoned from the fact that the average of the therapeutic doses obtained by the multiple dose method in 10 patients with comparable degrees of congestive heart failure is 1.6 mg. This fact again indicates that the patient responds only when an optimum dose level is reached regardless of the size of the initial dose, the subsequent doses and the time interval between doses (six to twenty-four hours). Our evidence favors the slow rate of dissipation of digitoxin; otherwise it would be expected that the daily undivided dose method would require a larger average dose than the rapid type of digitalization.

The toxic dose was obtained in 11 of the 12 patients. One patient was able to tolerate 0.3 mg. for twenty-five daily doses without toxicity. Toxicity was noted in four to twenty days with a dose range of 1.6 to 8 mg. (average 3.8 mg.) and was similar to that noted from the multiple dose method.

SINGLE DOSE METHOD

Gold and his associates^{1c} introduced the single dose method for digitoxin and advocated a dose of 1.2 mg. followed in twenty-four hours by a maintenance dose for all patients regardless of age, weight, sex or degree of heart failure. It was deemed advisable, therefore, to include this method in this study. Eighteen patients with chronic auricular fibrillation in various degrees of congestive heart failure were given a single dose of 1.2 mg. of digitoxin and observed for twenty-four hours to note any signs of clinical improvement. With the exception of 1 patient, who was in severe congestive heart failure, all patients were previously observed for several days to eliminate the possibility of spontaneous clinical improvement with bed rest alone. The data on these patients are summarized in the table.

Adequate digitalization was obtained in only 3 patients (17 per cent). Two of these were in mild failure. Eight patients (44 per cent) showed slight evidence of digitalization as indicated by slowing of the ventricular rate and diuresis, but this response was inadequate for satisfactory clinical improvement. None of these patients would have been considered to be fully digitalized. Seven patients (39 per cent) did not pre-

sent any clinical effects from the single dose of digitoxin. One patient subsequently died before sufficient digitoxin could be administered, while in another patient an additional 2.1 mg. in divided doses was also insufficient, although a complicating acute pulmonary disease occurring subsequent to initial digitalization may have been the responsible factor for death.

Since the claim⁷ is made that "full digitalization" is possible with the single dose, an effort was made to determine the exact level of digitalization attained. The patient was "titrated" by administering a small dose of digitoxin at six hour intervals, twenty-four hours after the initial dose, until a satisfactory therapeutic response was obtained, and then continuing until minor signs of toxicity occurred. Eleven patients required 0.4 to 3.3 mg. (average 1.6 mg.) more than the initial 1.2 mg. to achieve a good therapeutic effect. The therapeutic dose in these patients ranged between 1.6 to 4.5 mg., averaging 2.7 mg. If the three patients who responded to 1.2 mg. are included the average therapeutic dose becomes 2.2 mg. An additional 0.9 to 6.9 mg. (average 3.8 mg.) was required to achieve toxicity. The toxic dose varied between 2.1 and 7.1 mg., averaging 4.6 mg.

COMMENT

The response of a patient to an optimum dose of any digitalis preparation depends on several factors, the most important of which are (1) the degree of congestive heart failure, (2) the theoretical maximum improvement possible with the underlying heart disease and (3) the precipitating cause of the congestive heart failure. This optimum dose is specific for each patient and it cannot be predicted. It also varies in the same patient from time to time as conditions change. The administration of an average dose for the treatment of any individual patient is not in the best interest of the patient because of the possibility that such treatment may result in incomplete digitalization or toxicity. The so-called average dose is selected because of the low incidence of toxic manifestations which it may produce. The possibility of toxicity following the administration of such an "average" dose is, therefore, not great. However, toxicity may occur and in the rare hypersensitive patient this may be serious. The primary object in adequate digitalization is to restore cardiac efficiency as quickly as possible. The "average" dose may act as a rough guide for digitalization, but it should not be relied on to digitalize completely any individual patient. This holds true particularly for the single dose method of digitalization with digitoxin. Only 3 of our 18 patients had a satisfactory therapeutic response with this method. It was subsequently necessary in 11 of the patients to administer an additional 33 to 275 per cent (average 133 per cent) of the original dose to obtain a therapeutic digitalis effect. In view of our experiences with the multiple and daily undivided dose methods, this was to be expected. The administration of a large initial dose has only the advantage that the total optimum therapeutic dose may be obtained a few hours sooner. If the optimum dose is exceeded but is still short of a toxic dose, digitoxin will not produce any earlier or greater response than would be produced by the optimum dose itself. It is important, however, to recognize that no satisfactory therapeutic response will be noted until the optimum dose for the individual patient is reached. This point should be arrived at as cautiously as possible because toxicity with digitoxin

‡Ventricular rate.

§Auricular fibrillation.

may be severe and it may persist for many days. It is for these reasons that we recommend the multiple dose method.

Our results and conclusions are at variance with those reported by Gold and his associates⁸ and more recently by Katz and Wise¹⁰ but are in accord with the experiences of Stewart.⁹ Reasons for this variance are not at once apparent, but they may be related to the selection of patients included for study. The original group of patients used by Gold and his co-workers¹² consisted of 14 subjects with regular sinus rhythm and 16 subjects with auricular fibrillation. The dose was determined by comparing the alterations of the S-T segment and T waves in the electrocardiogram produced by digitoxin and digitalis leaf in patients with regular sinus rhythm, while the ventricular rate was followed in the patients with auricular fibrillation. The two methods yielded similar results. The conclusion was reached that "the full digitalizing dose (to a point bordering on minor toxic effects) given at one time lies, in the average adult between 1 and 1.25 mg. or 2.4 to 3 cat units." However, only 2 of the patients with regular sinus rhythm and 8 of the patients with auricular fibrillation were in congestive heart failure, and in these the degree of failure was not mentioned. This may have been responsible for the low dose of digitoxin reported. The use of the electrocardiogram as a means of gaging the effective dose of digitalis is open to several objections. First, the changes in the S-T segment and T wave are merely manifestations of digitalis action which usually occur simultaneously with other effects of digitalis such as slowing of the ventricular rate or improvement in muscular efficiency. The occurrence of any one of these effects may be independent of the others, so that a patient may have satisfactory clinical improvement without electrocardiographic changes. Similarly, electrocardiographic changes may be observed without concomitant clinical improvement. That the majority of patients will have the electrocardiographic changes occurring in proportion to the dose administered may be true for digitoxin and digitalis leaf, but there is no such correlation when other glycosides such as digoxin and lanatoside C¹⁰ are used. A similar degree of improvement of cardiac status and maintenance could be achieved with either of these glycosides, even though electrocardiographic changes are not as great as when digitoxin or digitalis leaf are used. Second, as a guide for digitalization, the changes in the electrocardiogram cannot replace the need for establishing the dose clinically in patients. This fact has also been noted by Gold⁹ who has stated that "It takes about three times as much digitalis to bring about the full therapeutic effects in heart failure as to produce changes in the T wave, and there are some patients who show negligible changes in the T wave with doses of the drug sufficient to control heart failure, while others may show advanced T wave changes with doses of the drug which cause negligible effects in heart failure." Since the frequency distribution curve¹¹ obtained with the effect of digitalis on the T wave would suggest 1.2 mg. of digitoxin as the "average dose," according to the foregoing statement this dose is approximately one third that required for full therapeutic effects. This more closely approximates the figure obtained by us. Nevertheless, the same investigators continue to claim⁹ that 1.2 mg. is the "average full digitalizing dose."

Gold and his associates¹⁰ treated 213 patients with varying degrees of heart failure including patients with auricular fibrillation and regular sinus rhythm. However, it is not clear whether these patients were being treated for the first time or were being redigitalized. In view of the statement "they had been without digitalis for at least three weeks" it would appear that the latter was most likely. It has been our experience that such patients often require a much smaller dose of a digitalis preparation to obtain adequate digitalization. The same holds true for the report by Katz and Wise.¹⁰ Not only was their study performed on previously digitalized patients, but only 5 of their 15 patients presented any congestive heart failure. Furthermore, since their patients were kept at complete bed rest only on the day of digitalization, they did not exclude the possibility of response to bed rest alone.

The doses of digitoxin advocated by Gold and his associates for both initial digitalization and maintenance are not in accord with clinical experiences for the treatment of congestive heart failure. It is well known that a definite correlation exists between the dose required for initial digitalization and the dose required for maintenance. As a rule the larger the initial dose, the larger the maintenance dose; yet 1.2 mg. of digitoxin, which is relatively a small dose, is advocated for initial digitalization, while 0.2 mg., a high dose, is recommended for maintenance. Perhaps this relatively high daily dose is required to supplement the therapeutic effects initiated with the single dose of 1.2 mg. and what is observed is not maintenance but cumulative digitalization. Since between 50 and 60 per cent of patients² can be maintained without toxicity on this high daily dose of digitoxin, it might have been assumed that this dose is a satisfactory maintenance dose. However, it is usually twice the minimal maintenance dose and approximately 30 per cent of patients² taking this dose for ten to twelve weeks will manifest signs and symptoms of toxicity.

We must disagree with the statement¹² that the incidence of toxic effects when the single dose is given to a large number of patients is more important than the incidence of satisfactory digitalization. It is always possible to determine the largest single dose which will result in the smallest incidence of toxicity, but unless that dose results in satisfactory digitalization, all that has been accomplished is that a safe dose has been determined. An "average" dose may aid in achieving the optimum therapeutic dose, but it can not be relied on to produce adequate digitalization.

It has been frequently emphasized that the so-called single digitalizing dose of digitoxin produces less local gastrointestinal irritation than an equivalent amount of digitalis leaf. However, this is the case only when one compares the administration of a single large dose of digitoxin with an equivalent dose of digitalis leaf. The assumption is made that if digitalis leaf were not so irritating, a single large dose of the leaf would be preferable for digitalization. However, sufficient clinical experience with digitalis leaf has favored the administration of small multiple doses.⁶ The object of this method is to have a better control of dosage and to assure a more effective and safe digitalization rather than to avoid local gastrointestinal symptoms. With usual doses of digitalis leaf, the factor of gastrointestinal irritation is negligible.

We believe that the factor of absorbability from the gastrointestinal tract is also being overemphasized. It is desirable to know that a particular glycoside is ab-

10. Studies still in progress.

sorbed in sufficient amounts to exert a therapeutic effect and whether this effect can be achieved with a fair degree of dependability with a prescribed dose. However, it seems to us that this is of major consideration in the establishment of a maintenance dose but is not so significant in initial digitalization. The individual patient is given a digitalis preparation at regular intervals until a desired therapeutic effect is achieved or toxicity results. As long as absorption occurs and the intervals are so spaced that the rate of dissipation is not too rapid, sufficient cumulation will occur. A more completely absorbed preparation does not result in any faster digitalization unless that particular glycoside has a short latent period of action. This is not so with digitoxin. Clinically the time taken for digitalization orally with digitoxin is no shorter than that observed by the oral route with digitalis leaf, digoxin and other glycosides. On the other hand, variability in absorption may play a role in establishment of the maintenance dose.² The method of comparing the effects of a single intravenous dose of a glycoside with a single oral dose as a guide to completeness of absorption must take into consideration the following factors:

1. A determination of the minimum optimum therapeutic dose for each method of administration. This is important because, as stated before, considerably more of a digitalis preparation can be given beyond the optimum dose with the same therapeutic effect. We have found no evidence in the literature that such a comparison has ever been made with digitoxin. Thus the results of giving a single dose of 1.25 mg. of digitoxin orally and parenterally may be identical. It has not been demonstrated, however, that the patient would not respond to an equivalent degree to a smaller dose given parenterally. Within certain limits the results would be identical because the patient would respond to a dose as long as it is optimum or above. If absorption is identical as determined by effects, then the toxic dose should also be identical. Whereas 2 mg. of digitoxin orally results in minor toxicity in 32 per cent^{1a} of cases, there is good reason to believe that the incidence and severity of the toxicity with this dose would be considerably higher by the intravenous route.

2. The latent period and rate of dissipation. A rapidly acting glycoside like digoxin will produce its effects within a few minutes if the concentration reaching the heart muscle is within optimum limits. However, if the drug is rapidly dissipated, the slower rate of absorption from the gastrointestinal tract does not allow sufficient cumulation with a single dose to attain the same level of concentration at the heart muscle to give at any instant of time an effect comparable to the intravenous route. The drug may be completely absorbed, but this is overshadowed by its rate of dissipation. Digitoxin, on the other hand, is so slowly dissipated that an oral dose will attain an effective concentration comparable to that achieved with the same parenteral dose. With slowly dissipated glycosides which possess comparatively long latent periods of action, a sufficient concentration may be eventually reached to produce the same effect as the parenteral dose. With the more rapidly dissipated glycosides such as digoxin and lanatoside C, which possess a comparatively short latent period, a single dose will produce a strong effect almost immediately on intravenous administration, but when the same dose is given orally a similar effect can never be reached.

Digitoxin when used properly fulfils the criteria for a satisfactory preparation of digitalis. However,

one must be extremely cautious in its use because of the possibility of toxicity which on the basis of an extremely slow rate of dissipation may be serious and prolonged.

From our studies, digitoxin offers no particular advantage over digitalis leaf for the usual treatment of a patient with congestive heart failure.

The disadvantages in the use of digitoxin as discussed in this paper and our clinical studies with this and other purified digitalis glycosides² lead us to conclude that digitoxin is not the one of choice.

SUMMARY AND CONCLUSIONS

Three methods for the oral administration of digitoxin for the initial digitalization of the patient with congestive heart failure are compared. Regardless of the method used, an optimum dose is required for any specific patient before a therapeutic response is attained.

The average therapeutic dose for the multiple dose method was found to be 2.2 mg. as compared with 1.7 mg. for the single undivided daily dose and 2.7 mg. for the single large dose with supplementary administration of digitoxin.

The average toxic dose for the multiple dose method was found to be 4.1 mg. as compared with 3.8 mg. for the single undivided daily dose and 4.6 mg. for the single large dose with supplementary digitoxin administration.

"Full digitalization" was not considered to have been adequately obtained with the single large dose of 1.2 mg. of digitoxin since a satisfactory digitalization was obtained in only 17 per cent of the patients and 0.4 to 3.3 mg. (average 1.6 mg.) additional digitoxin had to be administered before the optimal therapeutic response was reached.

Reasons are presented for selection of the multiple dose method as the one of choice for administering digitoxin.

Digitoxin offers no particular advantage over digitalis leaf for the routine treatment of the patient with congestive heart failure. Because of its slow dissipation and the possibility of prolonged and severe toxicity, digitoxin is not in our opinion the glycoside of choice.

Retinitis Pigmentosa.—One of the common causes of blindness is retinitis pigmentosa. Ten years ago it could be said that in some pedigrees this disease was transmitted as a dominant, in others as a recessive of the ordinary type, occasionally as a sex-linked recessive. In 1936 I argued that some pedigrees showed partial sex-linkage . . . We can now say tentatively that one of the genes, the abnormality of which causes this condition, is carried in that segment of the sex chromosomes of which women possess two, and men only one; another, which may give dominant or recessive mutants, in that segment of the same chromosomes of which both sexes possess two; while other such genes, how many we do not know, are carried in the other chromosomes. It is reasonably sure that they control different processes. And this is borne out by the fact that the partially sex-linked recessive type is never associated with deafness, while one of the autosomal recessives is so associated.

Pathologists will have to work out the aetiology of the different genetical types. They can hardly hope to do so until they are distinguished, if, as seems probable, each gene controls a different process. And just as the methods for the cure of bacillary and amoebic dysentery are very different, so it is unlikely that the same therapeutic measures will succeed against diseases, however similar in their symptoms, which are due to different genes.—Haldane, J. B. S., *Proceedings of The Royal Society*, June 1948.

JARISCH-HERXHEIMER REACTION IN EARLY SYPHILIS

Treated with Crystalline Penicillin G

THOMAS W. FARMER, M.D.

Dallas, Texas

The transient intensification of the symptoms and signs of early syphilis shortly after the institution of treatment (the Jarisch-Herxheimer reaction) has been repeatedly observed after the administration of mercury, bismuth and arsenical drugs. In 1943 Mahoney, Arnold, and Harris¹ first described the same febrile and cutaneous reactions in patients with early syphilis within eight hours after the initial injection of commercial penicillin. Subsequently a number of observations concerning the various manifestations, the specificity, the incidence and the severity of this reaction in early syphilis treated with commercial penicillin were reported. No attempt is made here to compare the frequency and severity of Herxheimer reactions after the administration of bismuth and arsenical preparations with those occurring after administration of penicillin.

Between July 1946 and June 1947 a large group of patients with early infectious syphilis were treated with crystalline penicillin G in twenty cooperating clinics, including the Johns Hopkins Hospital, under the direction of the Syphilis Study Section of the United States Public Health Service. From case reports sent to the Central Statistical Unit by those clinics the incidence of this reaction was determined. A group of patients with relapsing early syphilis was studied at the Johns Hopkins Hospital to clarify the possible prognostic value of this reaction. The relationship of the reaction to the dosage of crystalline penicillin G was determined in order to evaluate the possible benefit to be derived from small initial doses of penicillin, which have frequently been given in an effort to prevent the reaction. The relationship of penicillin dosage to febrile reactions and also to the disappearance time of *Treponema pallidum* was studied with the hope of obtaining further information concerning the theoretic nature of the Herxheimer reaction.

MANIFESTATIONS

The usual symptoms and signs of the Herxheimer reaction in early syphilis include any one or combination of the following observations:

1. Systemic or febrile phase of the reaction: chilliness, elevation of temperature, malaise, headache and nausea.
2. Focal or cutaneous phase of the reaction: edema or pain in the primary ulcer, enlargement of, or pain in, the regional lymph nodes, intensification of a secondary eruption or of other local lesions or the development of generalized roseola in primary syphilis. All of these signs and symptoms occur between four and forty-eight hours after the initial injection of penicillin. Therefore, the Herxheimer reaction may be classified as one of the "immediate reactions" to penicillin, in contrast with "delayed reactions."

The manifestations of the reaction vary. One patient with primary syphilis may have a generalized macular eruption and no fever; another may have fever with no focal signs; a third may have an elevation of temperature with no subjective symptoms. Of the various forms of the reaction the elevation of temperature may be measured most accurately.

In addition to these frequent manifestations of the Herxheimer phenomenon, focal reactions of the cornea have been described during penicillin therapy in syphilitic uveitis.² Intensification of the inflammatory reaction in papular lesions of the cornea in patients with secondary syphilis was observed under the corneal microscope. This increase in the number of inflammatory cells associated with haziness and corneal precipitates was described as a part of the "histologic phase" of the Herxheimer reaction. Similar studies of the cutaneous lesions of secondary syphilis by the microscopic examination in repeated biopsies have revealed an increased inflammatory reaction in four to six hours after the administration of penicillin.³

The Herxheimer reaction has been observed after intramuscular,⁴ intravenous⁵ and oral⁶ administration of penicillin in early syphilis. It has been noted following the use of peanut oil and wax suspensions⁷ and of aqueous solutions of penicillin.

Scott and Clark⁸ have reported the development of a transient nephrotic syndrome in a patient with early syphilis treated with penicillin, which they considered an unusual manifestation of a Herxheimer reaction. There is little evidence presented for this assumption, since the complication developed on the thirteenth day after the first injection of penicillin and on the fifth day after the completion of treatment. This represents a "delayed reaction."

SPECIFICITY

An evaluation of the specificity of the Herxheimer reaction in response to penicillin in early syphilis depends on accurate data concerning the incidence of febrile and cutaneous reactions following the administration of penicillin in other diseases.

In the treatment of primary and secondary yaws with penicillin, both febrile and cutaneous reactions have been reported.⁹ Temperatures of 100 to 104 F (37.8 to 40 C.) occurred in one half of 200 patients from two to eight hours after penicillin therapy was started. Thus, the Herxheimer reaction has been observed in this closely related spirochetal disease.

Herxheimer reactions have not been reported in a wide variety of acute generalized infections treated with penicillin. Since most of the patients in these

groups were already febrile, it was difficult to exclude the possible occurrence of secondary fever superimposed on an underlying febrile course. However, febrile reactions to penicillin among an analogous small group of cases of secondary syphilis with fever have been observed.⁵ In such cases, this reaction could be clearly delineated only when there was a maximal febrile response.

Patients with uncomplicated gonorrhea represent a satisfactory control group for the observation of possible febrile reactions to penicillin therapy, since these patients are usually afebrile. In a report¹⁰ of the results of the treatment with penicillin of 675 hospitalized women with gonorrhea, a mild rise in temperature during treatment was noted in only 2 patients, and both of these women had concomitant early syphilis. The frequency of observations of temperature in this group of cases was not stated. Thus, although adequate control groups are not available, it is said that early febrile reactions to the administration of penicillin to patients with nonsyphilitic infections are rare, if not nonexistent. The point requires further investigation.

In contrast with the apparent specificity of the febrile type of response, immediate cutaneous reactions to the administration of penicillin have been observed in patients with nonsyphilitic infections. Focal and generalized cutaneous reactions, occurring between ten and twenty hours after the injection of penicillin, have been noted in 18 (25 per cent) of 73 patients with various types of dermatitis (eczematoid dermatitis, atypical lichen planus and undifferentiated dermatitis).¹¹ Two types of reaction occurred, either a local exacerbation of the cutaneous condition, with hyperemia, pruritus and exudation of serum, or a generalized erythematous eruption. It was suggested by the authors, on the basis of results of cutaneous tests with penicillin and trichophytin antigen, that these reactions might be due to sensitization from a past or present fungous infection. Similar reactions in lesions of fungous origin have been described after the administration of penicillin.¹² The same increased inflammatory reactions which have been reported in syphilitic uveitis were also noted in 25 per cent of 36 patients with nonsyphilitic uveitis following the institution of penicillin therapy.² Thus, focal reactions to the administration of penicillin do occur in nonsyphilitic patients, and these might be clinically indistinguishable from the focal Herxheimer reactions in early syphilis.

RESULTS

Incidence.—With commercial penicillin, febrile reactions have been observed in 30 to 70 per cent of adults with early syphilis,¹³⁻¹⁵ and in 43 to 55 per cent of infants with congenital syphilis.¹³ The incidence of cutaneous reactions has not been accurately determined. Although the phenomenon has been reported to the Central Statistical Unit by the cooperating clinics in from 2 to 10 per cent of cases, this certainly is an underestimate of the true incidence of focal reactions. The "histologic phase" of the reaction has been observed in 70 per cent of patients with syphilitic uveitis.²

The incidence of febrile reactions following the administration of crystalline penicillin G¹⁴ was studied among a group of 939 patients with early infectious syphilis treated in twenty cooperating clinics. These patients were treated with initial doses of 25,000 to 50,000 Oxford units and with total doses of 2,400,000 to 4,800,000 Oxford units of penicillin administered intramuscularly. Temperatures were recorded every four hours.

TABLE 1.—*Relationship of the Incidence of Febrile Reactions to the Race and Sex of Patients with Early Syphilis Following Treatment with Crystalline Penicillin G*

Race	Total No. Treated	No. with Febrile Reactions	Percentage with Febrile Reactions
White	180	85	46
Negro	753	299	40
Total	939	384	41
Sex			
Male	498	207	42
Female	441	177	40
Total	939	384	41

Of this group, 384 (41 per cent) had febrile reactions (table 1). No significant race or sex differences in the incidence and severity of febrile reactions were demonstrated (table 1).

Relationship to the Stage of Early Syphilis.—Febrile reactions have been reported to occur when penicillin is administered during the incubation period of syphilis. Two patients¹⁵ have been observed in whom elevations of temperature were recorded during penicillin therapy for uncomplicated gonorrhea. At the time of treatment, their reactions to serologic tests for syphilis were negative. Secondary syphilis developed in these patients on the twenty-fifth and thirty-fifth days after penicillin therapy. Similar observations¹⁶ concerning the possible occurrence of the Herxheimer reaction during the incubation period of syphilis have been reported of 66 patients with early syphilis who gave a history of gonorrhea treated with penicillin during the possible incubation period of syphilis. Of these 66 patients, 18 gave a history of fever or chilly sensations accompanying penicillin therapy for gonorrhea. Thus, there is presumptive evidence that Herxheimer reactions to penicillin do occur during the incubation period of syphilis. However, it is not known how early in the incubation period such reactions occur nor how frequently they develop.

The relationship of the incidence and severity of febrile reactions to the stage of early syphilis among 800 patients treated with crystalline penicillin G is shown in table 2. Febrile reactions were observed with equal frequency and severity in patients with seronegative primary, seropositive primary and secondary syphilis. The incidence of this phenomenon was 39 to 43 per cent in these three groups of cases. The height of the febrile response was just as great in the group of patients with seronegative primary syphilis as it

was in the groups of patients with seropositive primary and secondary syphilis (table 2).

Relationship to Relapse.—The occurrence of Herxheimer reactions in relation to relapse was studied among 395 patients with early syphilis treated with commercial penicillin at the Johns Hopkins Hospital. In this group there were 56 cases of mucocutaneous relapse. Each of these patients with relapse had an initial early syphilitic infection followed by a relapse

TABLE 2.—*Relationship of the Incidence and Severity of Febrile Reactions to the Stage of Early Syphilis in Patients given Crystalline Penicillin G*

Type of Febrile Reaction	Sero-negative Primary Syphilis		Sero-positive Primary Syphilis		Secondary Syphilis		Total	
	Number Treated	Percentage	Number Treated	Percentage	Number Treated	Percentage	Number Treated	Percentage
Fever—All Grades	46	39	92	43	195	42	333	42
Grade I (0 to 1 F. rise)	23	19	36	17	113	24	172	22
Grade II (1 to 2 F. rise)	9	8	23	11	49	11	81	10
Grade III (2 to 7 F. rise)	14	12	33	15	33	7	80	10
No febrile Reaction	71	61	124	57	272	58	467	58
Total	117	100	216	100	467	100	807*	100

*Of the 939 patients presented in table 1, there was complete data concerning the stage of early syphilis for 800.

treated with a second course of penicillin. The total doses of penicillin varied from 600,000 to 4,800,000 Oxford units. Most of the medicaments given to this group consisted of many different lots of commercial penicillin from several manufacturers. A few of the patients with relapse were treated with crystalline penicillin G. Temperatures were recorded rectally every four hours, and a temperature above 100 F. (37.8 C.) was considered to represent a febrile reaction.

In the 395 patients, 188, or 48 per cent, had Herxheimer reactions. Among those 188 patients with febrile reactions, relapsing infections occurred in 28, or 15 per cent. Among the 207 patients without reactions, relapses occurred in 28, or 14 per cent. The duration of follow-up study in these two groups was similar. Thus, in these patients the relapse rates were approximately the same in patients who did and who did not have Herxheimer reactions during the first course of treatment.

Of the 56 patients with relapse, 28, or 50 per cent, had febrile reactions with the first course of treatment, and 21, or 38 per cent, had reactions at the time of re-treatment. There was no tendency for Herxheimer reactions to recur in the same half of this group. All combinations of occurrence of febrile response were noted with similar frequency: febrile reactions with both treatments (10 cases), no febrile reaction with either treatment (17 cases), fever with the first treatment only (18 cases) and fever with the second treatment only (11 cases).

Relationship to Dosage.—In the few observations concerning dosage which have been reported in early syphilis¹⁷ and in infantile congenital syphilis,^{18a}

no relationship between the incidence of reactions and the size of the initial dose in a range of 1,000 to 50,000 Oxford units of penicillin has been observed.

In order to obtain more detailed information on this point, a group of 121 patients with early infectious syphilis was studied at the Johns Hopkins Hospital. In each case the diagnosis was established by the demonstration of *T. pallidum*. Those with fever prior to treatment were excluded from the study. The initial doses administered intramuscularly to these patients varied from 1 to 120,000 Oxford units of penicillin per kilogram of body weight. In those patients who received more than a single dose within the first twenty-four hours, the amount given during the first six hours of treatment was arbitrarily chosen as that amount responsible for the Herxheimer reaction (table 3). Temperatures were recorded rectally every two hours, and a rise above 100 F. (37.8 C.) was considered significant.

TABLE 3.—*Relationship of the Incidence of Febrile Reactions to the Dosage of Crystalline Penicillin G Administered to 121 Patients with Early Syphilis*

Penicillin Dosage given in First 6 Hours	No. of Patients	No. with Febrile Reactions	Percentage with Febrile Reactions
Mg./Kg. Units/Kg.			
13-80* 20,000 = 120,000	9	5	56
2.6† 4,000	34	16	47
1.3† 2,000	22	12	55
0.075‡ 57 = 112	18	8	44
0.013 20	10	4	40
0.007 10	10	4	40
0.003* 5	8	0	0
0.007* 1	10	0	0

*Single dose only in the first forty-eight hours.

†Therapeutic doses repeated every two hours.

‡Three divided doses in the first six hours and no further penicillin for forty-eight hours.

The incidence of febrile reactions over a wide dosage range (10 to 120,000 units per kilogram of body weight) of penicillin varied from 40 to 56 per cent, with no definite trend in relation to dosage. However, when doses of penicillin of less than 10 Oxford units per kilogram of body weight were given, febrile reactions were no longer observed.

Pattern of Fever.—The pattern of the febrile response was studied in the 49 patients who had shown Herxheimer reactions (table 3). Since temperatures had been recorded every two hours in this group, detailed observations of the time of onset, height and duration of fever were available. These factors were analyzed in the following three groups: 5 patients who received large initial doses, 28 patients who received average therapeutic doses and 16 patients who received small doses of penicillin (table 3).

The temperature curves of 28 patients with febrile reactions in response to average therapeutic doses of penicillin (2,000 to 4,000 units per kilogram of body weight) were studied. The average temperature curve of this group is shown in figure 1. The febrile responses followed a uniform temporal pattern, with the height of the fever as the chief variable. The earliest elevation of temperature occurred four hours after injection. By six hours 72 per cent of the group had febrile rises above 100 F. (37.8 C.), and at eight hours 90 per cent of them showed a rise in temperature. The maximal elevations were recorded between six and ten hours

17. Footnote 4a. Olansky, S.: The Herxheimer Reactions of Relatively Small Doses of Penicillin. *J. Ven. Dis. Inform.* 28: 26-27 (Feb.) 1947.

after injection in 90 per cent of the group. In 2 cases the maximal febrile responses occurred between twelve and sixteen hours after injection. All of the temperature recordings were normal within twenty-four hours after the first injection.

The average temperature curves of 5 patients with febrile reactions following large initial doses (20,000 to 120,000 units per kilogram of body weight) and of 16 patients given small initial doses (10 to 112 units per kilogram of body weight) of penicillin are pre-

Fig. 1.—Average febrile reactions following the use of crystalline penicillin G in early syphilis in relation to initial dosage. (The broken line represents reactions to doses of 20,000 to 120,000 units per kilogram of body weight [5 cases]; the unbroken line represents reactions to doses of 2,000 to 4,000 units [28 cases], and the dotted line represents reactions to doses of 10 to 112 units [16 cases].)

sented in figure 1 for comparison with the group given therapeutic doses. Over this wide dosage range the pattern of the febrile reaction did not change. The earliest onset of fever was four to six hours after the injection was given, with the largest as well as with the smallest doses of penicillin which produced a reaction. The maximal elevations of temperature were recorded between six and ten hours after the injection was given in each of these groups, and the average heights of the fever (101.5 to 102 F. [38.7 to 38.9 C.]) were approximately the same. All of the temperature recordings were normal within twenty-four hours after the first injection over this dosage range. The individual maximal temperature recorded in the large initial dosage range was 103.4 F. (39.7 C.) at eight hours after the injection was given; in the therapeutic dosage range, 105 F. (40.6 C.) after six hours, and in the small dosage range, 104.2 F. (40.1 C.) after six hours.

The similarity of the pattern of fever in response to small doses and also to therapeutic doses of penicillin is further illustrated in figures 2 and 3.

Relationship to Disappearance of *T. Pallidum* from Lesions.—Observations were made on the relationship of the Herxheimer reaction not only to the dosage of penicillin administered but also to the disappearance of *T. pallidum* from dark field positive lesions in the same group of patients. With 300 to 120,000 Oxford units of penicillin per kilogram of body weight, early lesions became dark field negative between nine and thirteen hours after the initial injections in all cases.¹⁸ Six to ten hours after the injection was given febrile reactions occurred in one half of these patients. With 100 to 150 Oxford units of penicillin per kilogram of body weight, lesions became dark field negative after longer time intervals, which varied from eighteen to forty-eight hours after administration of the injection. In a low dosage range (10 to 80 units per kilogram of body weight), results of dark field examinations remained persistently positive for forty-eight hours. However, Herxheimer reactions occurred after the same

time interval and in the same proportion as observed with larger doses. Only with minute doses of penicillin (1 to 5 units per kilogram of body weight) were febrile reactions not observed. Thus, Herxheimer reactions occurred with doses of penicillin as little as one tenth of the minimal amount required to render lesions dark field negative.

Fig. 2.—Double Herxheimer reaction following the use of crystalline penicillin G in a 62 year old white man. The diagnosis was secondary syphilis.

Double Herxheimer Reaction.—Eight patients, who had shown febrile reactions to small single doses (10 to 20 units per kilogram of body weight) of penicillin (table 3), again experienced febrile reactions when

Fig. 3.—Double Herxheimer reaction following the use of crystalline penicillin G in a 19 year old Negro boy. The diagnosis was seropositive primary syphilis. The reaction followed the use of penicillin for the original infection. No febrile reaction occurred after the administration of the drug for infectious relapse.

they were given either a therapeutic dose or a repeated small dose of penicillin twenty-four to seventy-two hours later. This double Herxheimer reaction is illustrated in figures 2 and 3. The temporal pattern and the height of the second febrile reactions were similar to those of the first. In these patients results of repeated dark field examinations remained positive for *T. pallidum* in the time intervals between the first and second doses.

This reduplication of the reaction was not observed after repeated large single doses of penicillin. Five

18. Tucker, H. A., and Robinson, R. C. V.: Disappearance Time of Treponema Pallidum from Lesions of Early Syphilis Following Administration of Crystalline Penicillin G., *Bull. Johns Hopkins Hosp.* 80: 169-173 (March) 1947.

patients, who had shown febrile reactions to large initial doses (20,000 to 120,000 units per kilogram of body weight) of penicillin (table 3), were given therapeutic doses (2,000 to 4,000 units per kilogram of body weight) of the drug twenty-four to seventy-two hours later. None of these patients showed a second febrile reaction. Results of dark field examinations in this group of patients became negative for *T. pallidum* within thirteen hours after the first injection was given.

COMMENT

The use of the febrile Herxheimer reaction as an aid in the diagnosis of undetected early syphilis has been described by several authors.¹⁹ They have reported cases of unsuspected syphilis in which the diagnosis was made only after a Herxheimer reaction, occurring during penicillin therapy for gonorrhea, tonsillitis or other infection, had called attention to this diagnostic possibility. In some patients the diagnosis was missed because of the unusual location of the chancre or because it was concealed by inflammatory phimosis. In other cases the diagnosis was seemingly excluded by negative results of dark field examination and/or negative reactions to serologic tests for syphilis. When such patients were treated for concurrent infections with penicillin, the observation of febrile reactions was of some aid in the diagnosis of syphilis.

The fact that the reaction occurs only in approximately half of the patients treated with penicillin does place definite limitations on its practical use as an aid in diagnosis. When the reaction occurs in its characteristic temporal pattern, it may be of some presumptive diagnostic value. However, the absence of a febrile reaction does not exclude the presence of syphilitic infection.

In early syphilis the symptoms of the Herxheimer reaction are minor and incidental ones, which do not require the interruption of treatment. However, in late syphilis severe reactions attributed to the institution of treatment with penicillin have been reported, and methods for the prevention of such potential hazards have been sought. The use of small initial doses of 1,000 Oxford units (20 units per kilogram of body weight) of penicillin has been suggested as a method of decreasing the incidence and severity of such reactions in the treatment of late syphilis. However, the observations presented here concerning the relationship of dosage to Herxheimer reactions in early syphilis, and also similar observations in cardiovascular syphilis²⁰ and in neurosyphilis,²¹ do not support the view that small initial dosage represents a method of preventing these reactions. Febrile responses occur in early syphilis with as little as 500 Oxford units (10 units per kilogram of body weight) of penicillin. Also, the repetition of small doses or the institution of therapeutic doses of penicillin after such an initial small dose is usually followed by a second febrile response. Thus, with small doses of penicillin one may obtain repeated Herxheimer reactions, but small dosage cannot prevent the reaction.

The mechanism of the Herxheimer reaction in early

syphilis is not known. However, this reaction has been generally ascribed to the sudden destruction, presumably by lysis, of large numbers of spirochetes and the subsequent liberation of breakdown products of proteins or of an endotoxin. If this hypothesis were correct, then the frequency and severity of the phenomenon would vary directly with the total number of spirochetes destroyed. This number, in turn, would be a function of the dosage of the antispirechetal drug employed and of the total number of invading organisms originally present. However, the following observations presented in this study concerning these two variables are in disagreement with this hypothesis:

1. Over a wide range of dosage (10 to 120,000 units per kilogram of body weight) of penicillin there was tremendous variation in the number of spirochetes destroyed. Nevertheless, the incidence and severity of febrile reactions were remarkably constant.

- (a) Febrile reactions repeatedly occurred in patients given small initial doses (10 to 80 units per kilogram of body weight) of penicillin, which, as judged by results of serial dark field examinations of superficial lesions, destroyed smaller numbers of spirochetes than were killed with large doses.

- (b) The administration of large initial doses (20,000 to 120,000 units per kilogram of body weight) of penicillin did not increase the incidence or severity of Herxheimer reactions. Even with these large doses certain patients failed to show any reaction whatsoever, in spite of the fact that all detectable superficial spirochetes were destroyed within nine to thirteen hours after the injection was given, just as they were in patients who did have reactions.

2. Febrile reactions to the administration of penicillin were as frequent and as severe in seronegative primary syphilis as in secondary syphilis. This observation suggests that the reaction is not directly dependent on the total number of spirochetes originally present in the body, which may be presumed to increase from the date of infection until the height of florid secondary syphilis.

The observations presented here concerning the mechanism of the Herxheimer reaction suggest that in addition to the two factors already discussed (the number of invading spirochetes and the dosage of the antispirechetal drug), a third factor, namely, the reactivity of the host at the time of treatment, plays a dominant role in this phenomenon. At some time during the incubation period of syphilis the number of spirochetes present in the host increases to a quantity sufficient to produce a reaction. Therefore, a certain unknown minimal number of spirochetes is a first requisite. Secondly, a minimal amount of an antispirechetal drug (e.g., at least 10 to 20 units of penicillin per kilogram of body weight) is needed. Further increases in the number of spirochetes or in the dose of the drug above these threshold levels appear to play no further role in the mechanism of the reaction. Thus, this reaction, is an "all or none" type of phenomenon. When a threshold level of dosage is reached, the reaction occurs in about half of the patients. However, a third important set of unknown variables in different persons with syphilitic infections separate the reactors from the nonreactors. Further observations on the mechanism of this reaction are desirable.

SUMMARY AND CONCLUSIONS

Febrile Herxheimer reactions were observed in 41 per cent of 939 patients with early infectious syphilis treated with crystalline penicillin G. No race or sex

differences in the incidence of febrile reactions were noted.

Febrile reactions were observed with equal frequency and severity in seronegative primary, seropositive primary and secondary syphilis.

In a group of 56 patients with relapsing secondary syphilis treated with penicillin, the incidence of fever was 50 per cent with the first and 38 per cent with the second course treatment. Recurrent reactions were no more frequent in those whose first course of treatment was attended by a febrile reaction than in those who had had no fever the first time.

Within a wide range of penicillin dosage (10 to 120,000 units per kilogram of body weight) the incidence of febrile reactions remained relatively constant (40 to 56 per cent). With extremely small doses of penicillin (1 to 5 units per kilogram of body weight) febrile reactions were not observed.

The temporal pattern of the febrile reaction was rather uniform and was independent of the dosage over a wide range.

Febrile reactions occurred with single doses of penicillin as little as one tenth of the amount required to render syphilitic lesions dark field negative.

With repeated small doses of penicillin (10 to 20 units per kilogram of body weight) two febrile reactions were produced in the same patient. This double Herxheimer reaction was not observed after repeated large doses of penicillin.

The mechanism of the Herxheimer reaction from penicillin in early syphilis is not clear. It is suggested that the available evidence does not justify the hypothesis that the reaction is due solely to the sudden destruction of large numbers of spirochetes with the liberation of split proteins or endotoxins.

Further studies of the phenomenon are desirable.

THERAPY OF CHRONIC "ATROPHIC GASTRITIS" WITH EIGHT YEARS' GASTROSCOPIC CONTROL

LEONIDAS H. BERRY, M.D.

and

T. JONATHAN COLE, M.D.

Chicago

The anatomic entity known as chronic "atrophic gastritis" may be observed gastroscopically to improve or disappear from the stomachs of patients having pernicious anemia after liver therapy. Since the initial report of this observation by Jones, Benedict and Hampton¹ in 1935, several other reports² have appeared in the literature. In addition, gastroscopic changes in the atrophic gastric mucosa of patients without pernicious anemia have been observed by several investigators after specific types of therapy. Some of the substances used are desiccated hog's stomach ("ventriculin") by Schiff and Goodman,³ liver and

iron by Schindler, Kirsner and Palmer⁴ and others,⁵ thiamine by Bower⁶ and others, and the separate components of the vitamin B complex by Shapiro and his associates.⁷ Each of these studies was made on extremely small groups of patients and followed over relatively short periods of time. Some observers reported disappearance of atrophy with or without recurrences, while others have reported no changes.

Our studies began in 1938 with 60 patients. Excluding those on whom insufficient data were obtainable, we are here reporting the observations on 36 patients who received therapy and a control group of 16 patients who had no specific therapy or on whom therapy was started after a control period. The observations were both clinical and gastroscopic and extended over varying periods up to eight and one-half years. The chief differences between our study and those reported in the literature are as follows: (1) a much longer observation time, (2) more gastroscopic examinations and (3) the use of a control group and control periods, which were not carried out in most of the other studies. It was felt that in dealing with such a chronic disorder, longer periods of observation should have distinct advantages. The importance of controls and frequent examinations is obvious.

Our patients were all of the poorest economic class, indigents who had experienced a long period of unemployment and a longer period on the rolls of relief agencies during the years leading up to 1938. As indicated by dietary questionnaires, the food intake of these patients was considerably below the standards of normal nutritional requirements, both as to quantity and quality. Their undernutrition was further evidenced by plasma ascorbic acid levels below 1 mg. per hundred cubic centimeters in 95 per cent of the cases; low grade hypochromic anemia and varying degrees of loss of weight. However, on the basis of physical examination alone the entire picture might have been missed because of the sparseness of physical evidence of frank deficiency disease. It was observed by one of us⁸ that there was a greater incidence of so-called atrophic gastritis in a series of 702 patients who underwent gastroscopy prior to 1941 than that reported by other workers in this field. For example, Schindler⁹ found among 1,000 dyspeptic patients at the Billings Hospital in Chicago that 32.5 per cent of the chronic gastritis seen was of the atrophic type, while in our own series the incidence was 53.6 per cent.

It may be necessary to state here that while patients of the lowest economic level seem to have the highest incidence of atrophic gastric mucosa, it does not necessarily follow that persons of the highest economic level will escape such gastric changes. It should not be overlooked that many persons to whom adequate quantities and qualities of food are available have capricious appetites and eat only foods which appeal most to their tastes. Also it is probably true that there are some gastric atrophies which are not of dietary origin either directly or indirectly.

1) consisted of 10 patients who received injections of 1 cc. of vitamin B complex¹⁰ intramuscularly each day for twelve injections. Such a course was repeated three to four times, and gastroscopy carried out at the end of each course. Larger doses were given in some cases when indicated for the desired effect. Gastroscopy was performed for months and up to seven years after cessation of therapy. Four of these patients underwent gastroscopy an average of twelve times in eight to nine years; 3 patients average nine examinations in five to seven years, and 3 others averaged seven examinations from seven to two years.

The second group (tables 2, 3 and 4) consisted of 18 patients who received injections of liver extract¹¹. Ten of them received daily injections in courses simi-

twelve times each.

In the group given vitamin B complex in 7 out of 10 cases atrophy disappeared; in 4 cases it returned to some degree. The remaining 3 cases showed improvement, 1 with regression.

In the group given liver extract in 12 out of 18 cases atrophy completely disappeared; in only 2 cases did it return. The addition of iron or dilute hydrochloric acid did not bring about improvement greater than daily administration of liver extract alone.

"Nicamin" (monoethanolamine nicotinate),¹¹ containing 50 mg. of nicotinic acid, was given in daily doses—intramuscularly to 4 patients—and observations were made from six months to seven years (table 5). Two cases showed disappearance and return of at-

lar to those of the vitamin B complex in group 1. Four patients received 3 cc. of liver injections once a week and 1 Gm. of ferrous sulfate per day orally. The 4 remaining patients in this group received weekly in-

rophy. One case of pronounced arteriosclerosis showed no changes.

Dilute hydrochloric acid alone was given to 4 pa-

11. The "nicamin" and liver extract were supplied by Abbott Laboratories, North Chicago, Ill. Liver extract contained 5 pernicious anemia units per cubic centimeter.

tients over a period of six months to three and one half years (table 6). No changes occurred in 3 of these patients, but atrophy disappeared after one year of therapy in the remaining patient. This may not be a spontaneous remission, since 2 control patients observed for one year each showed no improvement in atrophy.

SYMPTOMATIC RESULTS

Symptomatically there was a most dramatic improvement after the daily injection of liver extract, vitamin B complex and nicotinic acid. Improvement but less dramatic results occurred after administration of dilute hydrochloric acid. Beneficial effects were

lated to gastric changes. The constipation, general abdominal bloating, dizziness, etc., could very well be related to the bowel. Such symptoms are well known in vitamin B complex deficiencies. The nervousness, weakness, anorexia, etc., may be related to the nervous system or more general metabolic disturbances. The symptom complex seems definite enough and sufficiently different from that of pernicious anemia with gastric atrophy to warrant designation as a definite syndrome.

No Return of Atrophy.—In summary, the gastroscopic results of our studies were as follows: The daily injections of liver extract give the best and most per-

usually experienced by the end of the second week. The symptoms¹² complained of in order of frequency were epigastric pain, aching, fulness, tenderness, burning, cramping, bloating and belching shortly after meals and especially after heavy foods, constipation, nausea with occasional vomiting, anorexia, dizziness, generalized weakness often in attacks, loss of weight, loss of strength and energy, nervousness, tremor in the epigastrium, feeling of heat in the epigastrium. All these symptoms were alleviated either partially or completely. Occasionally there was some moderate return

manent results. Some cases observed gastroscopically up to seven years with no further therapy, but improved diet, showed no return of gastric atrophy. One or more instances of complete disappearance of atrophy occurred in each therapeutic group. There was no spontaneous decrease of atrophy in any of the 16 control patients who either received no specific therapy or were on control periods up to twelve months. In a few cases atrophy disappeared almost completely and showed no further improvement or regression over a period of years.

of symptoms, but none of the patients felt as ill as before therapy. After Pearl Harbor, practically all these patients became gainfully employed. More food and a greater variety of it was available. Most of them soon gained in weight and strength, and their improved symptomatic status continued through the remainder of the eight years' period of observation. These observations strongly suggest a dietary deficiency as the cause of gastric mucosal atrophy. It appears unlikely that a local inflammation of the gastric mucosa should cause the multiplicity and variety of symptoms described. It is more probable that the symptoms are caused by a generalized metabolic or nutritional deficiency syndrome of which gastric mucosal atrophy is only a part. The epigastric distress may be directly re-

Recurrences of Atrophy After Disappearance.—Our patients also showed some recurrences of atrophy. Of interest is the fact that of the 6 patients showing recurrences of atrophy, 4 were moderate alcoholic addicts (cases 12 and 33, table 1, and cases 7 and 4, tables 2 and 3 respectively). These patients continued to drink moderately during the entire period. Atrophic changes decreased and partially returned even during therapy, only to decrease again. This observation does not prove, however, that the changes were due to the irritation of the alcohol, in our opinion. There is the strong possibility that the atrophy might have been due to substitution of alcohol for food, in which case the recurrent atrophy would still be of dietary origin.

No Improvement of Atrophy after Therapy.—Only 4 of our patients failed to show improvement after therapy. Two had received dilute hydrochloric acid

12. A table showing incidence of symptoms was compiled but was not submitted for publication.

only. The third was a woman, aged 65 (case 10, table 5), with pronounced generalized arteriosclerosis. She received extensive injections of liver extract, followed by vitamin B complex and then nicotinic acid over a period of one year without any improvement in the

gastroscopic picture of atrophy. She had been seen in the clinic for two or three years before gastroscopy, and her dyspeptic symptoms had been explained on the basis of "abdominal arteriosclerosis." It appears that the atrophy in this case was due at least in part to the arteriosclerosis and diminished blood supply to the gastric tissues and was therefore little affected by any of

the therapy employed. The other patient was one who also had adrenal cortical insufficiency.

Gastric Mucosal Atrophy and Chronic Superficial

therapy the superficial gastritis would disappear leaving the more slowly healing atrophy (cases 12 and 33, table 1). This process has been seen to repeat itself in the same person in several instances. The point therefore arises that the simultaneous occurrence of chronic superficial changes and atrophic changes does not invariably indicate that chronic superficial gastritis has progressed to chronic atrophic gastritis. We believe that in many instances these findings represent chronic superficial gastritis, superimposed on an atrophic gastric mucosa of nutritional deficiency origin. The differentiation is important because the term "atrophic gastritis" implies a local inflammatory disease. Gastric mucosal atrophy seems to be in most instances a manifestation of a generalized deficiency state requiring an entirely different approach in therapeutic management.

OTHER INTERESTING FACTS IN THE EIGHT YEAR STUDY

One patient with an extensive atrophy of the gastric mucosa was observed to have pernicious anemia four years later. During five years in the clinic previously he had shown no evidence of anemia. In this case, atrophy of the gastric mucosa is known to have preceded pernicious anemia by at least a few years. With one exception, all the patients reported in this study survived the development of gastric cancer, in spite of their atrophic gastric mucosa for at least eight years. The 1 patient died in another hospital of gastric carcinoma seven years after the initial gastroscopic finding of mucosal atrophy. Gastric mucosal atrophy might well have been the predisposing factor to cancer in this case. More cases of this kind which will be found only by long term follow-up studies might eventually settle the question of the relationship between gastric mucosal atrophy and gastric cancer.

CONCLUSIONS

(1.) Further evidence of the therapeutic response of gastric mucosal atrophy to nutritional substances is presented. (2.) After nutritional therapy, prompt and dramatic relief of the entire symptom complex occurs; it may not return in seven years or more if a normal diet is followed. (3.) Atrophic gastric mucosa may regain and maintain normal appearance for seven years or more when followed by a normal diet.

(4.) There is a high incidence of gastric mucosal atrophy among economically poor and malnourished patients: (5.) Gastric mucosal atrophy in patients without pernicious anemia seems to be a part of a generalized "nutritional deficiency syndrome" rather than a local

inflammatory disease and warrants specific designation. (6.) Gastric mucosal atrophy may precede pernicious anemia and gastric carcinoma by several years.

DISTINCTIONS BETWEEN GASTRIC
SARCOMA AND CARCINOMAWith Special Reference to the Infiltrating
Types of Sarcoma

ANTHONY BASSLER, M. D.

and

A. GERARD PETERS, M. D.

New York

This article is based on a series of 20 cases of advanced sarcoma of the stomach confirmed either by operation or autopsy. We are concerned with the various signs, symptoms and laboratory findings which could aid in making a preoperative diagnosis of gastric sarcoma. These features are compared and contrasted with similar features found in advanced carcinoma of the stomach. We believe that sarcoma of the stomach could be diagnosed more often. In this series of sarcoma 11 cases were lymphosarcoma, 3 were of the spindle cell variety and 6 were round or mixed cell alveolar sarcomas. In 11 of the 20 cases features were present to warrant a supposition that sarcoma rather than carcinoma existed.

Pathologic distinctions of gastric sarcoma based on tissue derivation, while scientifically valuable, can be made only by microscopic examination. It is generally accepted that the cytologic and embryologic variations of sarcoma present no distinctions clinically; indeed, it probably always will be impossible to make a diagnosis of gastric sarcoma with qualification as to its cellular architecture.

Ewing's¹ estimate that sarcoma comprises 1 per cent of malignant tumors of the stomach is widely cited. More recently, Marshall and Aronoff² reported an incidence of 3.2 per cent in 464 patients operated on for gastric tumors at the Lahey Clinic. In 1944, at the Mayo Clinic, of 298 malignant lesions of the stomach, 3.3 per cent were sarcoma.³ Phillips⁴ reported that in persons under 30 years of age sarcoma comprised about 6.5 per cent of malignant gastric lesions. Thus it appears that sarcoma of the stomach is encountered more frequently than is generally assumed.

Ewing's¹ classification of gastric sarcoma is widely employed: (1) spindle cell myosarcoma; (2) lymphosarcoma, and (3) miscellaneous round cell or mixed cell alveolar sarcoma. Of these, lymphosarcoma is the type most frequently seen and comprises about 60 to 65 per cent of sarcomas encountered in the stomach.⁵ It arises from the lymphoid tissue in the submucosa and usually infiltrates widely along the stomach wall into the muscularis and may penetrate the serosa causing perforation. This also holds true for some types of sarcoma in the miscellaneous group. The spindle cell myosarcomas are usually solid tumors, arising from the curvatures, and may protrude into the stomach or extragastrically.⁶ They usually occur as circumscribed masses with well limited boundaries.

Ulceration usually occurs rather late in the course of gastric sarcoma and is caused either by vascular strangulation or pressure atrophy of the mucosa due to tumor formation in the submucosa. Usually the tumor spares the orifices; therefore dysphagia and pyloric obstruction are rare as compared to carcinoma. In reviewing the location of 100 cases of sarcoma of the stomach, D'Aunoy and Zoeller⁷ listed their positions as follows: greater curvature, 17; pyloric region, 16; lesser curvature, 16; posterior wall, 12; diffuse infiltration, 11; anterior and posterior wall, 11, and anterior wall, 6. The remaining were situated on either the anterior or posterior wall and one of the curvatures, and only one was situated in the fundus.

A modification of Schlesinger's⁸ clinical classification of gastric sarcoma is offered: (1) the exogastric, arising in the outer coats (or courses to the outer coats) but little involving the organ intragastrically; (2) intragastric, projecting in the lumen as an isolated growth, and (3) infiltrative type, which involves the stomach wall profusely and which may or may not project intragastrically.

DIFFERENTIATION OF GASTRIC SARCOMA
FROM CARCINOMA

Age—The average age for persons with gastric sarcoma reported by D'Aunoy and Zoeller⁷ in 135 cases was 36.7 years. Balfour and McCann⁹ reported an average age of 43 years. In our series it was 38.5 years. These contrast with the average age of persons with carcinoma of the stomach, who are about ten to fifteen years older. This, however, should not be given too much significance because the age of our patients ranged from 18 to 78 years. Relatively, however, the younger the patient with malignant disease of the stomach, the greater is the probability of sarcoma.

Sex—Bockus¹⁰ stated that sarcoma is only slightly more prevalent in the male. In the 135 cases reviewed by D'Aunoy and Zoeller⁷ 73 of the patients were male and 43 female and in the remainder there was no information as to sex. Askey¹¹ and others in reviewing 335 cases reported 70 per cent occurring in males. In our series 75 per cent of the patients were male. The incidence of carcinoma in the sexes does not differ materially from that of sarcoma.

Duration of Symptoms—In sarcoma of the stomach symptoms may be present from two months to several years. In inoperable cases, the average duration of symptoms is thirty-seven months.¹² In our cases it was twenty-nine months. In carcinoma the average duration of symptoms is eight to twelve months. In sarcoma there is no relationship with previous peptic ulcer, while about 5 to 10 per cent of prepyloric gastric ulcers became carcinomatous.

Pain—Pain is the most common symptom; it occurred in 80 per cent of our cases. It is localized in the left upper quadrant, or tends to the left, although it may be epigastric completely. The pain is often more severe than that seen in carcinoma.⁶ In about 50 per cent of the cases the pain simulates peptic ulcer,¹³ but

this is not significant as it is often seen in carcinoma. The distinction, however, between relief of pain in ulcer and the two malignant diseases of the stomach is that in the latter there is progressive loss of weight.¹² In an analysis of 444 patients with gastric carcinoma, pain was present in 92.8 per cent.¹⁴ Thus, pain is the most common symptom in both sarcoma and carcinoma. In a general way, it seemed to us that pain tended to be more severe in sarcoma, although there were 4 cases in which pain was absent.

Weakness, Cachexia and Anemia—Weakness, Cachexia and Anemia are generally grouped together in the literature, which makes it rather confusing on each of these points. Bockus¹⁰ stated that anemia, loss of weight and strength and other constitutional symptoms occur with about the same frequency as in carcinoma. Rafsky and his associates¹³ stated that they were usually absent in lymphosarcoma of the stomach. Madding¹⁵ in reviewing 67 cases of sarcoma states that some patients complained of loss of weight, weakness and anorexia and that anemia (microcytic, hypochromic) was present in most cases but was not as great as in carcinoma. Drane¹⁶ stressed the well preserved nutrition in cases of gastric sarcoma. In our opinion the symptoms of weakness, loss of weight, cachexia and anemia should not be grouped because individually they have varying degrees of differential diagnostic value. One is often struck by the surprising well-being of a patient with advanced sarcoma of the stomach. In our group of 20 patients, 12 (60 per cent) were employed at the time of examination. The remaining 8 patients complained of definite weakness. In roughly the same stage of carcinoma of 100 patients, weakness was present in 94 per cent. The same differential occurs concerning loss of weight. In carcinoma of the stomach, loss of weight is progressive and usually severe. Slight and short weight increases may occur, but a continuing decline soon supervenes. In sarcoma, the loss of weight was pronounced in only 7 of our patients. Eleven had lost a negligible few pounds and 2 had no definite loss of weight.

That the nutty brown color so characteristic of gastric carcinoma does not occur in sarcoma is a clinical point of interest. The skin is pallid and its appearance is that of a simple anemia. Very occasionally one sees a slight lemon tint as noted sometimes in leukemia.

There are no worth while points to present in the type or degree of anemia between the two diseases. The anemia may be slightly less in sarcoma. In 444 cases of carcinoma of the stomach, jaundice was present in 23.2 per cent.¹⁴ It was absent in all our cases and we have seen no mention of its occurrence in sarcoma in the literature.

Vomiting and Hematemesis—Vomiting occurs in 8 to 10 per cent of gastric sarcoma,¹⁷ and in 16 per cent of carcinoma.¹⁴ Hematemesis is encountered in 15 to 20 per cent of sarcoma and about 10 per cent in carcinoma. It is important to remember that in sarcoma vomiting and hematemesis occur late probably because pyloric obstruction is less frequent than in carcinoma and the mucosa is secondarily involved in sarcoma. Bleeding in sarcoma is often severe and may be terminal.

Palpable Tumor—It is reported that a mass may be

palpated in 30 to 50 per cent of gastric sarcoma.¹⁸ In carcinoma this percentage is 80 per cent after the third month of symptoms. This difference is due to the fact that the largest percentage of sarcoma is infiltrative in character and thus may not form a definite, easily felt mass. Therefore the sarcoma may be of large extent and yet not be palpable. A sense of deep, diffuse resistance may be encountered rather than a localized hard mass and may be mistaken for a tumor of the pancreas, colon or kidney. In our 20 cases a tumor was palpable in 10. If the roentgenogram shows an extensive involvement of the stomach and no tumor is palpable, or only a doughy mass is observed, sarcoma should be suspected.

An enlarged spleen is palpable in 10 per cent of gastric sarcomas.¹⁰ In our series the lower pole of the spleen was palpated in 3 (15 per cent). Palpable spleens are rare in carcinoma.

Virchow's gland, sometimes palpable in gastric carcinoma, is not observed in sarcoma. Visible gastric peristalsis, characteristic of pyloric obstruction, was not observed in our series.

Gastric Analysis—It is reported that 85 per cent of gastric carcinoma shows an absent or low free acidity.¹⁵ Madding and Walters² stated that in lymphosarcoma of the stomach there is achlorhydria in the largest number of cases and that normal acid values are found in but 20 per cent. In our series 8 had acid values which were normal or above normal and 12 had decidedly lowered or absent free hydrochloric acid. Of these 12 patients showed no free hydrochloric acid but did have some combined hydrochloric acid (not total acid). Five were achylia. Therefore, there were 15 of 20 patients (75 per cent) who had hydrochloric acid (free or combined) in the gastric juice. This is distinctly higher than that observed in gastric carcinoma.

Blood in gastric contents and stools is encountered in about 65 per cent of carcinoma of the stomach.¹⁴ All observers believe that the percentage is much lower for sarcoma. This is due to the fact that ulceration occurs much later in sarcoma and may be absent throughout the course of the disease. In our group of cases, blood was encountered in 4 instances. Death from exsanguination, however, is more frequent in sarcoma.

Gastroscopy—Schindler¹⁹ stated that the infiltrative type of lymphosarcoma presents characteristic gastroscopic findings which cannot be mistaken for any other picture. This statement has not been accepted generally. Giere²⁰ reported a case of lymphosarcoma diagnosed gastroscopically one month after the roentgenogram had failed to disclose any abnormality. In solid tumors, the endoscope may disclose a solitary tumor with a sessile base, the rest of the mucosa appearing normal. (If the tumor is pedunculated, it probably is benign). In the infiltrative type of sarcoma, the gastric rugae are swollen and edematous. Later, ulcers and hemorrhages may be noted. The picture is not as characteristic as in carcinoma. Gastroscopy was performed in 16 of our cases. In 10 of these cases the diagnoses were: benign tumor 4, gastritis 2, Hodgkin's disease 2, leukemic infiltration 1 and tuberculosis 1. In the remaining 6 cases sarcoma was strongly suggested, all of which were instances of lymphosarcoma. The method should be employed, and it is of

especial value when its presumptive diagnosis of sarcoma agrees with that of the roentgen examination.

Roentgenographic Findings—The roentgen examination, properly conducted, is the most reliable method for diagnosis available. Rugal patterns should be studied with small quantities of barium. There should be adequate manipulation and palpation at roentgenoscopy. The fluoroscope is valuable especially in noting the solitary growths or masses projecting into the stomach, presence or absence of peristalsis and stiffening of the gastric walls. The statement that a positive diagnosis of sarcoma cannot be made by roentgen rays²¹ or by any method short of exploration and biopsy¹⁰ constantly runs through the literature. Rafsky and his associates¹³ reported a definite roentgen diagnosis in 33 per cent of their series of lymphosarcoma. In our own series 11 of the 20 cases (55 per cent) were presumptively diagnosed as sarcoma. This percentage compares with a positive roentgen diagnosis of 90 per cent in carcinoma of the stomach.¹⁴ There are points of difference in the roentgen findings of these two malignant diseases of the stomach.

Gastric deformities to be observed in sarcoma include the following: (1) a rounded, well defined endogastric mass, bearing a demonstrable ulcerative niche²²; (2) a tumor arising on the greater curvature, even when it has the typical saucer shape of carcinoma; (3) giant rugae; (4) diffuse decrease in the size of the stomach; (5) absent or few "thumb indentations" characteristic of carcinoma, with the irregularity in gastric outline consisting of shallow serrations involv-

regular in outline; masses may be seen in carcinoma between the curvatures; when present in sarcoma, it is usually late in the disease, and while the tumor may be of large size (especially leiomyosarcoma) there is usually a small fleck of barium somewhere in the mass; most cases of sarcoma may never show a definite well defined tumor mass; (7) peristaltic waves are dependent on the amount of infiltration of the gastric wall; if intramural infiltration is extensive, peristalsis will be absent; however, in sarcoma, peristalsis, sluggish or irregular, is usually preserved later than in carcinoma. In our series, as already stated, a presumptive diagnosis of sarcoma rather than carcinoma was made in 55 per cent. A notable error is that shown in figure 1 (a case of Dr. Adolph Abraham).

Another unusual case of hypertrophic gastritis that closely simulated the roentgen picture of malignant growth is illustrated by figure 2 (case of Dr. Harry Barowsky).

Fig. 1.—Carcinoma diagnosed as sarcoma because of diffuse tumor formation and some shallow serrations of curvatures. There was no obstruction. Pathologic diagnosis was colloid carcinoma. On reexamination of films after operation it was noted that the growth is intragastric, the left half of the stomach appears normal and the defect on the greater curvature is more suggestive of carcinoma.

Fig. 2.—Deformity due to giant hypertrophic gastritis.

REPORTS OF CASES

The following 4 cases illustrate various features of gastric sarcoma.

CASE 1.—F. S., (a patient of Dr. Charles Friels, Jersey City), a farmer, 35 years of age, had been in good health until eleven months before being examined by one of us (A.B.). His illness began with anorexia, which became progressively worse. Three months later he began to complain of pain in the upper left part of the abdomen and vomited occasionally. There was a weight loss of 12 pounds (5.4 Kg.) over this period. Physical examination revealed no significant abnormality. No abdominal mass was palpable. Several test meals revealed normal values in the gastric contents, and in some a hyperchlorhydria existed. There was a mild degree of hypochromic anemia. Roentgen examination disclosed an isolated mass in the prepyloric region with no generalized involvement of the stomach. There was about 10 per cent gastric retention in six hours. Gastroscopecally, a mass with a sessile base was seen and a few punctate hemorrhages were scattered in the mucosa. Because of the wide base by which the

ing the stomach to considerable extent; (6) in localized sarcoma, a shadow may occur which is suggestive of benign tumor; at fluoroscopy it is not movable and usually is well rounded; in benign tumor the shadow is liable to be pedunculated, movable and ir-

22. Carter, R. A. and Laing, D. R.: Non-Carcinomatous Tumors of the Stomach, *Radiology* 28:301-314 (March) 1937.

tumor was attached, a tentative diagnosis of solitary gastric sarcoma was made. At operation (subtotal gastrectomy) the tumor was removed and the pathologic diagnosis was spindle cell sarcoma. The patient died twenty-two months later from metastatic sarcomatous masses in the lungs, abdomen and subcutaneous tissue.

Comment—This case illustrates pronounced anorexia, slight loss of weight, absence of abdominal mass and normal gastric acidity. Roentgenograms revealed an immovable intragastric mass.

CASE 2.—L. M., a young man of 18 years weighing 181 pounds (82.1 Kg.) complained of anorexia of four months' duration. "To get enough food" he had to resort to fluids and semisolid foods. He had lost 5 pounds (2.3 Kg.) over this period. There were no other complaints, he attended school regularly and engaged in athletics. Because his mother thought he looked pale, he was treated for moderate anemia. When first seen he presented slight nonpainful resistance in the epigastrium and mild hypochromic anemia; his gastric contents had a normal acidity. His stomach was extensively involved with infiltration of the walls and a diagnosis of gastric sarcoma was made. At operation an extensive partial gastrectomy was performed; the tissue diagnosis was lymphosarcoma. He died on the fourth postoperative day of an abdominal hemorrhage.

Fig. 3.—The stomach shows a generalized infiltrative process in the wall with diffuse decrease in size and irregular serrations on the curvatures. There is no obstruction. Lymphosarcoma.

Comment—This case illustrates the occurrence of lymphosarcoma in youth, slight loss of weight, absence of constitutional symptoms and presence of normal gastric acidity.

CASE 3.—W. R., (a patient of Dr. Pettit, Ridgewood, N. J.), a banker 68 years of age, had been troubled for ten years with a squamous cell carcinoma of the face. He had had a number of excisions, roentgen and radium treatments and when first seen had a large inflammatory area over the left ear. The upper third of the left external auricle was sloughed away, exposing the cartilage. During the preceding year he had lost considerable weight (14 pounds [6.4 Kg.]) and a mild degree of weakness had developed, although he was able to work. There were no gastric symptoms until six weeks before examination, when he became slightly nauseated and had diarrhea, both of which persisted. On examination, there was a soft diffuse

mass (stomach) palpable in the epigastrium and extending to the right. The spleen was palpable and the liver edge firm and rounded. The red blood cells were 4,100,000, and there was 11 Gm. of hemoglobin per hundred cubic centimeters. The

Fig. 4.—Diffuse infiltration in the distal half of both curvatures with narrowing of the gastric lumen. Lymphosarcoma.

white blood cells were 9,100, with 74 per cent polymorphonuclear cells. An Ewald test meal revealed no free hydrochloric acid. Total hydrochloric acid was 25 degrees and total acidity

Fig. 5.—Showing the general stiffening of the stomach in a case of lymphosarcoma. Irregular formation is noted about two thirds down along the lesser and greater curvatures indicating the general involvement of the stomach walls.

31 degrees. Roentgen examination revealed a generalized infiltration throughout the stomach with no apparent masses or obstruction. There was a mild degree of cardiospasm. A diagnosis of lymphosarcoma was made. At operation almost a

complete gastrectomy was performed; the stomach was diffusely infiltrated by the sarcomatous process and there was chronic adenitis of the omental lymphatic nodes. The patient died eight weeks postoperatively of acute heart failure, after he had seemed to be slowly improving.

Comment.—This case is interesting because of the coincidental squamous cell carcinoma, short history of gastric symptoms, small loss of weight and palpable spleen. Hydrochloric acid was present in the gastric contents.

CASE 4.—A. J. (a patient of Dr. Emil J. Knips, Plandome, L. I.), a woman aged 49, mother of seven children, had a carcinoma removed from her breast ten years previously. Two years before being seen she began complaining of "nervousness" and pain in the region of the stomach. This pain became progressively worse for ten months. On physical examination a generalized doughy tumor was palpated in the upper part of the abdomen. Because of the character of the roentgenograms and a 4 plus Wassermann reaction, a diagnosis of gastric syphilis was made three months previously, and she had been placed on antisyphilitic therapy without benefit. She had lost only a few pounds in weight, was not anemic, had a fair appetite and consumed ample foods of all types, which, she said, did not increase her stomach distress or pain. She had vom-

Fig. 6.—High power photomicrograph of tissue of the stomach, showing cells of various shapes and sizes with extremely large cells containing large nuclei and nucleoli predominating. In places these cells are spindle shaped and show characteristic tiny fibrils. Mitotic figures are noted throughout. Leiomyosarcoma.

ited only twice, both times in the week before being seen by one of us (A. B.). Physical examination revealed the tumor described. An Ewald test meal showed hyperchlorhydria. The stools were negative for blood in several examinations. Roentgenograms showed a generalized stiffening of the stomach walls with absent peristalsis and with a mass in the pyloric region. The gastroscopic diagnosis was lymphosarcoma. The portion of the stomach with the tumor mass was removed. The pathologic report was leiomyosarcoma. The operation was followed by roentgen therapy over the stomach region. She died three months after the operation in the New York Hospital from a massive gastric hemorrhage.

Comment.—This case, which was originally diagnosed as gastric syphilis, illustrates but slight loss of weight with fair appetite. No anemia was present. There was hyperchlorhydria, and death was due to massive hemorrhage. This patient also had a carcinoma of the breast ten years before.

GENERAL COMMENT AND CONCLUSIONS

It is important in considering tumors of the stomach to realize that about 85 per cent are carcinoma. Rigler and Ericksen²³ stated that 11 per cent are benign, as noted earlier in this paper, slightly over 3 per cent are sarcomas. Even this figure of 85 per cent is high when one includes syphilis, tuberculosis, Hodgkin's disease, etc. If the possibility that a gastric malignant growth is not carcinomatous is continually entertained, the first and most important step toward the accurate presumptive diagnosis of gastric sarcoma is achieved. A careful evaluation of the various symptoms, signs and laboratory findings will, in increasing numbers, lead to a higher percentage of correct preoperative diagnoses. From the present group of cases and the literature on malignant disease of the stomach, we can draw the conclusions summarized in tables 1 and 2.

TABLE 1.—Clinical Symptoms (in Percentages)

	Sarcoma	Carcinoma
Age (years)	38.5	53
Sex, male	75	70
Duration of symptoms (months)	29	8-12
Previous history of peptic ulcer	0	5-10
Pain	80	92.8
Weakness (definite)	40	94
Weight loss (pronounced)	35	98
Cachexia	0	92
Jaundice	0	23.2

TABLE 2.—Physical, Laboratory, Gastroscopic and Roentgen Findings (in Percentages)

	Sarcoma	Carcinoma
Palpable tumors	50	80
Firm tumors	30	85
Soft (doughy) tumors	70	15
Palpable spleen	15	0
HCl, normal, increased	40	15
HCl, absent, low (combined)	60	85
Blood in gastric contents and stools	20	65
Suggestive gastroscopic diagnosis	37	75
Suggestive roentgen findings	55	90

In favor of a diagnosis of gastric sarcoma as compared to carcinoma in an average way, the following points are noted:

1. Average age for sarcoma is 38.5 years; in carcinoma it is fifteen years older.
2. Because of slowness of the growth, sarcoma may extend twice or even three times longer than carcinoma.
3. There is no relationship with peptic ulcer in sarcoma.
4. Weakness in cases of sarcoma is less than half that of carcinoma.
5. Loss of weight is about one third that noted in carcinoma. In sarcoma there may be only slight anemia or none. In carcinoma it is more definite.
6. No jaundice is present in sarcoma; in carcinoma it occurs in 23.2 per cent.
7. Palpable tumor in sarcoma is a little more than half as common as in carcinoma. The sarcoma masses are vague and doughy in consistency, whereas in carcinoma, generally, the mass is easily felt and firm to hard in character. Visible peristalsis is not noted in sarcoma.
8. The spleen is enlarged in 15 per cent of the cases of sarcoma and not present in carcinoma.
9. Vichow's gland is not observed in sarcoma.
10. Hydrochloric acid of the free and combined types was present in 75 per cent of sarcoma; this figure is much higher than that found in carcinoma.
11. Blood in gastric contents and stools is observed in one third of the cases as compared to carcinoma.

23. Rigler, L. G., and Ericksen, L. G.: Benign Tumors of the Stomach, Radiology 26:15 (Jan.) 1936.

12. The gastroscope is less valuable in diagnosing sarcoma than carcinoma.
13. The roentgenograms are valuable in both conditions, although less so in sarcoma than in carcinoma.
14. Roentgen evidence suggestive of sarcoma is present in 55 per cent of the cases.

Recognizing that various combinations of findings are different in different cases, we would suggest a working formula as follows: (1) roentgen; (2) clinical findings and gastroscopy; and (3) laboratory. If the roentgenograms are definitely suggestive of sarcoma we would make a diagnosis. If the roentgenograms are not characteristic of carcinoma or sarcoma, we would give increasing importance to the features listed under (2) and (3), and if enough suggestive findings are met with we would make a presumptive diagnosis of sarcoma. One must keep in mind that in some cases of gastric sarcoma diagnosis is not possible even at operation without a microscopic examination of tissue.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. BERRY AND COLE AND
DRS. BASSLER AND PETERS

DR. HYMAN I. GOLDSTEIN, Camden, N. J.: In 1920 and 1921 I studied the available literature of the world in preparation for papers on lymphosarcoma of the appendix. At that time I collected about 650 cases of primary sarcoma of the gastrointestinal tract, liver, pancreas and gallbladder. There were about 270 cases of primary sarcoma of the stomach, 18 of the appendix, about 150 of the intestines, 36 of the esophagus, 65 of the tongue, 16 of the gallbladder, 59 of the liver and 19 of the pancreas. Obstructive symptoms, occurring late in the course of the disease, are not uncommon in young patients. Symptoms may be absent for some time or only slight. Gastric lesions may become large and extensive before severe loss of weight and obstruction occur. Taylor (1939), Madding (1939), Collins and Carmody (1937) and others recently reported interesting cases of gastric sarcoma, as did Johnson, Lee and others, who stated, "Lymphosarcoma of the stomach is not a rare neoplasm." Their patient was a man aged 23 years. Dr. George Dock reported a case of "Sarcoma of the Stomach" while at Ann Arbor. The man was 55 years old. A successful gastrectomy was performed (1900), although he had the tumor for nearly two and one-half or three years. This patient lived until 1919. He died from pneumonia and had had no gastrointestinal symptoms for nearly twenty years! Halle's (1780-1781) case in a young woman with "Induration skirrheuse des membranes de l'estomac" was probably a gastric sarcoma. Since Mathis, in 1602, and Daniel Schwabe, in July 1635, performed successful gastrotomies, and Daniel Karl Theodor Merrem (1790-1859) of Giessen successfully resected the stomach in a dog (in 1810), we have made great progress in gastrointestinal surgery. We have overlooked the successful extensive resection of the intestines in a 13 year old boy by John Nedham (reported in 1756) and the first pylorotomy for cancer of the stomach, by Jules Pean (1830-1898) in 1879, before T. Billroth (1881). The speaker's report of about 28 or 30 five year survivals out of about 400 cases of gastric malignant growths is not encouraging. Perhaps early gastroscopy and earlier surgical intervention would save many more patients.

DR. HENRY A. RAFSKY, New York: I was interested in Dr. Berry's paper because I found that patients with atrophic gastritis improve when their nutritional status has improved. Dr. Bassler's paper is timely. Articles on these subjects should be encouraged because these so-called rare lesions, when we focus attention on them, are not as uncommon in an active ward

service as we think they are. Lymphosarcoma of the stomach is the commonest type encountered. This lesion often mimics peptic ulcer in its onset and in its clinical course. At times we found hyperchlorhydria, but what we did not find until late in the disease was occult blood in the stool or in the gastric analysis. The clinical characteristics of carcinoma of the stomach, weight loss, anemia and cachexia, were not usually present in our series. The reason that carcinoma of the stomach can be detected earlier than lymphosarcoma lies in the difference in the pathologic changes of the two lesions. Gastric lymphosarcoma often arises extragastrically and invades the stomach from a lymph node or starts within the lymphoid tissue of the submucosa. It may become a large tumor involving and surrounding the stomach, and may exist without causing any symptoms, or may form an infiltrating process of the submucosa, producing a picture of severe gastritis or giant rugae. In a suspicious case sarcoma should be suspected, especially if the characteristic symptoms associated with carcinoma are not present.

DR. RUDOLF SCHINDLER, Los Angeles: We must no longer treat gastric carcinoma as one single disease entity. At least two forms must be differentiated: the sharply limited ones, types I and II, and the infiltrative forms, types III and IV. The limited forms are curable; the infiltrative forms are, with rare exceptions, incurable. The limited carcinomas must be removed even if they involve the whole stomach. To attack the infiltrative forms, except if they are small, is not practical. These patients have almost no chance of being cured, except perhaps by total gastrectomy. This consideration is especially important in the management of benign gastric ulcer. The differential diagnosis never lies between benign ulcer and limited carcinoma but only between benign ulcer and infiltrative carcinoma. Benign ulcer can well be treated medically; the resection has a definite mortality. Let us assume that the operative mortality of benign ulcer is only 3 per cent, and let us see what happens if we resect 100 stomachs which contain a doubtful ulcer. We will then kill, unnecessarily, 3 persons, if the ulcers are benign, in order to accomplish what, if they are all malignant? Practically nothing. Let us better concentrate on surgery for small-sized, beginning gastric carcinomas, which the surgeon may not be able to palpate but which may be diagnosed by roentgen examination and gastroscopy. If we follow our cases of pernicious anemia and atrophic gastritis, as Dr. Berry has, we will have a higher percentage of cures by discovering small symptomless carcinomas.

DR. SAMUEL FRIEDMAN, New York: A large number of patients suffering from cancer consult their physicians when it is too late. Physicians do not always make a diagnosis early enough for the surgeon to do a successful operation. How can we relieve the unnecessary suffering and reduce the death rate from cancer? Years ago I realized that we must feel equally responsible to our patients to relieve them as to cure them. We must caution patients of the seriousness of the delayed diagnosis. We must not be caught unawares in the diagnosis of serious diseases. For the past fourteen years I have been inviting my patients, four or five times annually, to my home to listen to lay lectures on the early symptoms of cancer and to lectures on many other serious ailments. These lectures, given by physicians and surgeons, and by myself, were usually attended by between 300 and 400 patients. Motion pictures of abdominal surgery, roentgenograms of tuberculous lungs and sound motion pictures on the heart in health and disease were shown. It is the sacred duty of physicians to reduce the suffering and mortality rate by teaching patients in groups, in the manner suggested. Judging from personal experience, I believe that half of those who die from carcinoma could probably live, and in comfort, if all physicians earnestly followed this suggestion.

Clinical Notes, Suggestions and New Instruments

STOMATITIS DUE TO STREPTOMYCIN

Report of Three Cases

HILLEL BEHAM, M.D.

and

HERBERT PERR, M.D.

New York

Since the use of streptomycin has become widespread in the treatment of many infections in human beings, the question of its untoward side reactions assumes importance. To date, many reports of toxic reactions following its use have appeared in the literature.¹ One of the most constant of these reactions is temporary or permanent impairment of the eighth nerve apparatus.² No other neurologic involvement following streptomycin therapy has been reported. Local irritations at the site of injection,³ fever,⁴ dermatitis,⁵ pruritis, rhinitis, conjunctivitis,^{1b} swelling of the buccal mucous membranes, flushes,⁴ and eosinophilia have all been noted, either singly or in combination, and are considered manifestations of hypersensitivity to the drug. This report deals with 3 cases of painful stomatitis, at first resembling the aphthous variety, which developed during the treatment of pulmonary and extrapulmonary tuberculosis with streptomycin.

REPORT OF CASES

CASE 1.—L.B., a 55 year old man, was admitted to Montefiore Hospital on April 21, 1947, with the diagnosis of pulmonary tuberculosis. He had been in good health until midsummer of 1945, when he first noticed that his expectorations were occasionally streaked with blood. At that time, he had no fever, night sweats, thoracic pains or weight loss. A roentgenogram of his chest and an examination of his sputum revealed no abnormalities. He was asymptomatic for about one year and then noticed the gradual onset of fatigue and a slight loss in weight. In October 1946, a roentgenogram of the chest and sputum and bronchoscopic examinations revealed no abnormalities. In December, study of the sputum revealed acid-fast bacilli. Sudden hemoptysis, of about one-half glass of bright red blood, occurred on Jan. 14, 1947, and the patient was admitted to Morrisania Hospital, where he remained until his admission to Montefiore Hospital. In February, he received streptomycin for two and one-half weeks before its use was discontinued for nonmedical reasons.

The patient was known to have had diabetes for fifteen years, which was well controlled with insulin. He had had hemiparesis of the left side, for three years. There was no history of asthma, hay fever or urticaria. No one in his immediate family had allergic manifestations.

Physical examination revealed a slightly stout well developed white man in no discomfort, with no dyspnea, cyanosis or

palor. His chest was hypersthenic, with slightly diminished expansion on the right side. Fine rales were noted in the upper lobe of the left lungs, associated with harsh breath sounds and dullness to percussion posteriorly. There was slight facial weakness on the left and flexion paresis of the left forearm, with some atrophy of all the muscles of the left upper extremity. There was paralysis, of the upper motor neuron type, of the left lower extremity. Laboratory observations on admission were within normal limits. His sputum showed tubercle bacilli on direct smear.

Bed rest was prescribed until July 22, when 1 Gm. of streptomycin daily, 166 mg. every four hours, was prescribed. This dosage was maintained until August 26, when it was increased to 2 Gm. daily. On August 28, a generalized faintly erythematous nonpruritic finely papular rash developed, especially prominent on his back and abdomen. The next day he complained of pain in his mouth and throat, which was intensified by swallowing. At that time a few yellowish vesicles were visible on the mucous membrane of the cheeks, around the anterior pillars of the tonsils and on the inner surfaces of the lips. It was thought that this was nonspecific aphthous stomatitis, and warm saline gargles and the application of a solution of 1 per cent brilliant green in 50 per cent alcohol were prescribed. Despite medication, the vesicles eroded and were covered by a gray shaggy necrotic membrane. Smears and cultures revealed only a few fusiform and spirochetal organisms, in insufficient numbers to warrant the diagnosis of Vincent's disease. The presence of 10 per cent eosinophils on August 29 indicated the possibility of allergic stomatitis. The dermatologic consultant, Dr. Harry Keil, described the lesions as follows: Practically all of the buccal mucous membrane, as well as the vermilion portion of the lips, the undersurface of the tongue, the right pillar of the tonsil and extending into the pharynx, were sites of diffuse erosive stomatitis. The edges of some of the lesions showed a whitish membrane, but there was no definite evidence of bullae.

Treatment with streptomycin was discontinued on September 4, and remarkably rapid improvement occurred. In two days, the soreness and erythema had decreased, and within five days little evidence of the stomatitis remained. By this time the dermatitis had undergone fine desquamation on the back and extremities, with lamellar desquamation on the hands. Treatment with streptomycin was started again September 13, and after five doses (166 mg. every four hours) stomatitis, of the same character as previously described, recurred. In spite of cessation of treatment with the drug, it took fifteen days for all evidence of these oral changes to disappear. On September 18, the dermatologist stated that the disappearance of the eruption on the discontinuance of treatment with streptomycin and the recurrence of the stomatitis on retreatment with the drug, were definite proof for the correctness of the opinion that this was due to stomatitis streptomycin.

CASE 2.—R.D., a 47 year old white man, was admitted to Montefiore Hospital on April 8, 1946. He had apparently been well until about fourteen months prior to admission, when nonradiating pain developed in the middle of the upper part of the back. A diagnosis of "rheumatism" was made, and then increasing pain and limitation of motion called for further investigation. A roentgenographic diagnosis of tuberculosis of the vertebra (Pott's disease) was made, and the patient was admitted to the orthopedic service.

His past history revealed no pulmonary infections, asthma, hay fever or urticaria. His father had asthma, of unknown causation, for thirty years.

Physical examination revealed some tenderness to percussion in the region of the fifth to the seventh dorsal vertebrae. On admission a roentgenogram of his back showed a probable tuberculous abscess, involving the sixth and seventh dorsal vertebrae. On April 27, a body cast was applied, with unsatisfactory results. A Hibb's fusion was performed on May 10, followed by an uncomplicated postoperative course. On August 16, some thoracic pain developed, and the patient produced blood-streaked sputum containing acid-fast bacilli. Examination revealed bubbling rales in the lower half of the right lung field. A diagnosis was made of erosion of a tuberculous mediastinal lymph node into a bronchus, with post hemoptotic

From the Pulmonary Division, Montefiore Hospital, New York. The streptomycin was supplied by Merck & Co., Inc., Dr. J. M. Carlisle, Medical Director.

spread. His pulmonary condition responded to bed rest, and recovery was uneventful until early March 1947, when an afebrile painless swelling of the left side of the scrotum developed. A diagnosis of tuberculous epididymitis was made, and on May 17 a rupture to the outside occurred, with the formation of a tuberculous scrotal sinus. On June 13, 1 Gm. of streptomycin daily, in six equal doses, was prescribed and was followed by gradual healing of the sinus.

On September 18, the patient complained of a feeling of tightness in his lips, mouth and throat, with some difficulty in swallowing. There was slight swelling of the mucous membranes of the mouth. Within two days an aphthous-like eruption developed, closely resembling that described in case 1 (the figure). Stomatitis due to streptomycin was suspected, and

Appearance of lesions on the third day of stomatitis, after the patient (case 2) had had 1 Gm. daily of streptomycin for ninety-four days.

treatment with the drug was discontinued on September 23. The dermatologist confirmed the resemblance of this stomatitis to that in case 1. A culture taken from an eroded lesion revealed *Staphylococcus albus* and *Streptococcus nonhemolyticus*; no fungi were present. The lesion had completely disappeared by October 3. Streptomycin was readministered on October 6, with the immediate subjective response of itching and tightness of the mouth. Within three hours slight swelling of the buccal mucous membrane was evident, and in twenty-four hours oral lesions like the lesion first noted had developed.

CASE 3.—S.S., a 50 year old white man, was transferred from Lebanon Hospital on Sept. 11, 1947, to Montefiore Hospital. Following pleurisy on the right side in 1937, a diagnosis of inactive minimal tuberculosis of the apex of the right lung was made. Roentgenologic studies and examinations of sputum were made at six month intervals, and for the first time, in January 1947, tubercle bacilli were seen in the sputum. Limited activity was prescribed until April, when, following a blow to his chest, substernal pain and shortness of breath developed. He sought no medical aid until July 2, when he was admitted to Lebanon Hospital with a diagnosis of coronary occlusion. The course of the disease was complicated by bilateral thrombophlebitis of the lower extremities and bilateral subdeltoid bursitis. On July 25, 2 Gm. of streptomycin daily were prescribed for his pulmonary infection. He had no untoward reactions until September 4, when dermatitis and painful stomatitis developed, but administration of the drug was continued until his admission to Montefiore Hospital.

Examination revealed a diffuse erythematous rash, with small reddish punctate papules. There were several small yellow vesicles in the mouth, predominantly on the inner aspect of the cheek and the vermillion border of the lower lip.

Because of the suspicion of dermatitis and stomatitis due to drugs, treatment with streptomycin was discontinued, and the lesions disappeared within a week. On September 17, 333 mg. of streptomycin were administered intramuscularly. Pruritus occurred immediately, and 50 mg. of tripeleannamine hydrochloride ("pyribenzamine hydrochloride") was given, with relief of the symptom. Following administration of a similar dose of streptomycin four hours later, generalized erythema developed, with a mild chill followed by a temperature of 103 F., and oral lesions developed, similar to those described in cases 1 and 2. After cessation of treatment there occurred gradual improvement of the stomatitis.

COMMENT

The pertinent data of our 3 cases are summarized in the table.

Summary of Data in 3 Cases

	Case 1	Case 2	Case 3
Dosage (Gm. daily)	1 and 2	1	2
Total dose (Gm.)	39	94	84
Institution of treatment	7/22/47	6/15/47	7/25/47
Occurrence of stomatitis	8/28/47	9/18/47	9/4/47
Duration of stomatitis (days)	14	15	13
Eosinophils (percentage)	10	6	8

The clinical picture presented in the 3 cases was identical: painful, erosive and membranous stomatitis, involving the entire oral mucous membrane as well as the undersurface of the tongue. Aside from the relatively mild cutaneous eruption in 2 cases there was no association of other toxic symptoms.

When the oral lesions were first noted and the bacteriologic examination revealed no significant pathogenic agent, the possibility of stomatitis due to streptomycin presented itself; treatment with the drug was discontinued, and the lesions disappeared within fourteen days. The diagnosis was not certain, however, until retreatment with the drug caused a rapid reappearance of the lesions.

While it appears that stomatitis was a late rather than an early reaction, it was not possible to correlate the lesions with such factors as the daily dosage, the total amount of streptomycin given or the duration of its administration.

SUMMARY

Three cases of severe erosive and membranous stomatitis are presented, which occurred during the administration of streptomycin for the treatment of pulmonary and extrapulmonary tuberculosis.

This lesion healed rapidly after treatment with the drug was discontinued.

The fact that the lesions reappeared promptly on resumption of treatment with streptomycin indicated that the stomatitis was caused by the antibiotic.

ACUTE EXFOLIATIVE DERMATITIS AND DEATH FOLLOWING PENICILLIN THERAPY

JACOB RABINOVITCH, M. D.

and

MORRIS C. SNITKOFF, M. D.

Brooklyn

It is not within the scope of this paper to review in detail the various toxic reactions which result from penicillin sensitivity, as this information is readily available in any of the numerous publications on the subject, but rather to discuss a few of the more salient factors which should be borne in mind when one is called on to use this drug. Many reactions to penicillin or to the toxic impurities contained in individual batches of the extract have been described in the literature. Among these pruritus, urticaria, vesicular and bullous dermatitis, chills, fever, headaches and gastrointestinal disturbances have been particularly emphasized. Fortunately, none of these reactions are of such severity as to jeopardize the life of the patient. Whether the sensitizing agent in a particular instance is the active principle of penicillin or other substance in commercial penicillin capable of producing sensitization is not known, although it is generally conceded that the active principle of penicillin itself is the provocative agent.

From the Departments of Surgery and Medicine, the Jewish Hospital, of Brooklyn.

It is now a well established fact that persons who are allergic to penicillin may have a wide variety of toxic reactions. It is the purpose of this contribution to call attention to the more severe toxic effects of penicillin and report a case in which death followed its therapeutic administration. So far as our knowledge goes, no instance of death due to penicillin has been heretofore reported in the literature.

REPORT OF CASE

A. G., a white woman aged 72, was admitted to the Jewish Hospital because of pains in the right lower part of the abdomen diagnosed as acute appendicitis. At operation, a gangrenous and perforated appendix was found and removed. In addition, the peritoneal cavity was found to contain free, turbid fluid, which when cultured, yielded a nonhemolytic streptococcus. Because of the latter finding and as a safeguard against the spread of the peritoneal infection, she was given 400,000 units of penicillin daily in divided doses for eleven days. At the end of this time she recovered fully from the operation and was discharged from the hospital afebrile and feeling well; the wound of operation had completely healed.

Four days after her discharge from the hospital and seven days after the last injection of penicillin, the patient began to complain of a general body itch. This was soon followed by the appearance of a maculopapular eruption which covered almost the entire skin surface of the body. A punctate, erythematous eruption also appeared over the palate which was rather painful. The temperature rose to 102 F., the pulse rate was rapid and the patient appeared acutely ill. She was given adequate doses of diphenhydramine hydrochloride but with no beneficial effects. Within the next few days the rash became more pronounced and appeared confluent, first over the face, and later also, over the chest and the rest of the body. Diphenhydramine was then discontinued and triphenylamine hydrochloride was substituted, but again with no apparent improvement. The temperature continued to remain at a high level; she soon began to vomit and complain of abdominal pain and distention. She was then given "amytal" (N. N. R.) and ephedrine, but again with no alleviation of symptoms. The blood count showed 10,000 leukocytes, 76 per cent of which were polymorphonuclear leukocytes, 5 per cent eosinophils and the remainder lymphocytes.

The course of her illness was progressively in a downhill direction. Acute conjunctivitis developed with pronounced swelling and edema of the face. The mouth showed numerous small areas of ulceration covered with an adherent gray exudate. The skin over the face, and later also over the remainder of the body, began to exfoliate and presented a picture characteristic of acute exfoliative dermatitis. The lungs became congested, and a severe hacking cough developed which was most disturbing.

The patient was readmitted to the hospital acutely ill; she was stuporous and incontinent. Breathing was stertorous and the lungs considerably congested. Numerous moist rales could be heard almost over the entire chest. The body was covered with a homogeneous, fiery red rash with multiple areas of giant bullae; some of the latter had ruptured and discharged a clear, serous fluid. The clinical picture presented now by the patient was similar to that seen in cases of extensive second and third degree burns. For this reason the patient was given blood plasma alternating with 5 per cent dextrose solution intravenously, together with vitamin B complex, vitamin C and adrenal cortex extract. In spite of all medication, however, her condition grew steadily worse. The temperature began to spike at a high level, reaching a peak of 105 F. Many more skin blebs appeared, which soon ruptured, leaving behind large oozing surfaces. Also a generalized jaundice developed which became evident first over the sclera and later over the entire skin. Because of the pronounced swelling and ulcerations over the cubital veins, little blood could be obtained for detailed chemical studies. The blood urea was normal; the blood count and sedimentation tests showed no significant changes. The patient finally lapsed into a deep coma from which she could not be aroused; she died thirteen days after the first appearance of the toxic symptoms and the skin rash.

COMMENT

This case illustrates a severe type of reaction in a person who is allergic to penicillin. It is of interest to note in this

connection that 2 of her children who received injections of penicillin for therapeutic purposes were equally sensitive to the drug and showed a most violent reaction. They both had headaches, nausea, vomiting, giant urticaria and fever which lasted for a period of three weeks before the symptoms subsided. Evidently, there exists here a familial sensitivity to penicillin. Unfortunately, this fact was not known to us at the time that the patient was treated with penicillin or careful scratch tests would have been done to determine the sensitivity of the patient to this drug.

The clinical picture presented by this patient merits some detailed comment, though in many respects it followed the pattern previously described by many authors. An analysis of the various case reports recorded in the literature, and of our own case, demonstrates rather clearly that there exists a latent period between the time of administration of the drug and the first appearance of symptoms. This time interval is estimated to be about five to twenty-one days; it was seven days in the present case. The ill effects of penicillin first became evident with the development of a general pruritus and the appearance of a cutaneous rash. In this respect the disease simulates closely other allergic reactions with cutaneous manifestations. The rash is not distinctive in itself and may be a macular, papular, urticarial, vesicular or bullous dermatitis. The vesicles have a tendency to rupture and leave behind raw, weeping surfaces. Cases of severe exfoliative dermatitis have been reported, most of which do not last more than three weeks. In the case under discussion the disease assumed a most fulminating character, causing death within two weeks following its onset.

While the cutaneous lesions dominate the clinical picture, other visceral manifestations may develop in the course of the disease and assume great significance. Of the various visceral disturbances, those affecting the gastrointestinal tract and the liver have received special emphasis. Many of the patients complain of general malaise, nausea, vomiting and abdominal pains. There are still numerous gaps in our knowledge of the precise nature of the anatomic changes produced in these organs by the action of penicillin. Unfortunately, permission for autopsy was denied in our case and therefore the exact nature of the pathologic changes produced by the drug in the various organs could not be determined. One is therefore reduced to speculation regarding the mode of action of penicillin on the gastrointestinal tract and other viscera. From our knowledge of the action of other allergins it may be surmised that similar anatomic lesions are also produced in the case of penicillin sensitivity. In the case of the gastrointestinal tract these changes consist of edema of the wall and sometimes also ulceration of the mucosa.

The development of jaundice in the course of treatment with penicillin suggests a hepatic lesion probably in the nature of a toxic hepatitis. Howells and Kerns¹ reported 47 cases of hepatitis in patients who were given injections of penicillin for venereal infections. These authors were not certain, however, that the penicillin was the direct cause of hepatitis. It was thought that the lesion in the liver was due to some icterogenic agent such as a virus, which was transmitted to the patient through faulty injection technique. There is no doubt however, that in the case under discussion the hepatitis was a direct result of the penicillin, to which the patient was unduly sensitive.

There is still considerable discussion as to whether the active principle of penicillin is the sensitizing agent, or whether some other substance present in commercial penicillin is capable of producing sensitization. Most observers are of the opinion that the active principle of penicillin is the causative factor, and such proof has been offered through various scratch tests in the human being as well as animal experimentation. We are also inclined to believe that penicillin itself is the sensitizing agent, in view of the fact that similar toxic reactions were exhibited by 3 different members of the family, in whom different batches of penicillin were used.

The evidence now at hand seems to justify the conclusion that the haphazard use of penicillin is not devoid of risk. Fortunately, few patients react to the drug in a manner to lead to serious complications or to result in death. Most of the toxic

CALORIC UNDERNUTRITION AND STARVATION, WITH NOTES ON PROTEIN DEFICIENCY

ANCEL KEYS, Ph.D.

Minneapolis

1. INTRODUCTION

Justifiable enthusiasm about discoveries of specific nutrients and their metabolic consequence has distracted attention from the oldest problem in nutrition—simple caloric inadequacy. General undernutrition, with or without major deficiencies of individual nutrients, has always been widespread in the world at large; the tragedy of famine periodically emphasizes how slender is the margin of safety. In the United States and Canada food production has been so abundant for many years that the direct impact of famine is unknown; the consequences of food shortages elsewhere, however, increasingly demand attention and effort here. Moreover, the importance of secondary undernutrition in disease is beginning to be realized.

Caloric undernutrition has been generally assumed to involve a parallel protein deficiency in most cases. In Asia, the area of most frequently recurring famine, the diet is low in protein in the best of times. Any food shortage quickly reduces such sources of proteins as are usually available, and subsistence depends almost entirely on rice, tapioca and other foods which contain little protein. In Europe the protein in the typical famine diet is almost all of vegetable origin. In any case, the severely undernourished person is necessarily in a state of negative nitrogen balance so there is at least some of the effect of a protein deficiency. The present discussion includes some remarks on protein deficiency (sections 7, 8 and 9).

Practical questions about general undernutrition raised by World War II clearly revealed the undeveloped state of this area in the science of nutrition. Generalities about metabolic balance, normal weight for height, and optimal food intakes are of small help in evaluating the actual degree of caloric inadequacy, in predicting the consequences of a specific dietary level and in planning and operating programs of relief and rehabilitation. This is a field in which the contribution of animal experimentation is necessarily small; quantitative translation from animal to man is dubious at best and impossible in terms of behavior, intellectual functions, work performance and many details which have great medical and social significance. The residue of useful data on man himself is surprisingly meager but has been greatly augmented in the past few years.

2. SOURCE OF INFORMATION

Limitations of animal experiments have been men-

tioned; besides the interpretive difficulty, the actual evidence from studies on animals is not great. On man there is a plethora of general impressions and observations from famine areas; besides frequent deficiencies in technical measurement, these reports usually provide only a description of the famine victims without information about their prestarvation characteristics or satisfactory details as to the dietary intakes which produced their present condition. The same strictures may be made about the clinical literature on cachexia. From a vast literature, however, many common points emerge; for the most part these can only be incorporated, without specific citation, in the present summary.

Studies on a few fasting persons constitute the classic literature cited under "starvation" in the textbooks. Acute experiments with no food at all are of great interest, but they have only relatively remote bearing on the problems of chronic undernutrition and the real conditions of famine. Another question is whether the professional fasters and fanatics who have been studied are reasonable representatives of the general population.

There have been two major experiments on prolonged undernutrition in man. The Carnegie Institute experiment¹ provided much information from a group of young men who voluntarily submitted to underfeeding for several months; the degree of semistarvation was small, as indicated by weight losses of only the order of 10 per cent. In the Minnesota experiment 32 young men lost an average of 24 per cent of their body weight in six months; the total period of study lasted almost two years.²

There are no recent full-dress reviews of undernutrition and starvation, but several older works are still of great value: Porter³ for a first-hand account, with many autopsies, of famine in India; Lusk⁴ for the metabolic problems; Morgulis⁵ for a discussion from the point of view of the biologist, and Jackson⁶ for an exhaustive treatment of morphologic aspects. Several recent papers provide good general pictures. Leyton⁷ reported observations in a prisoner of war camp where there were some elements of scientific control. Data on weight changes and mortality of internees in France are valuable.⁸ Summaries of data on accidental persons starved in Japanese camps are available.⁹ Useful vital statistics and estimates of dietary intakes in periods of famine are provided for Holland¹⁰ and for Greece.¹¹ Data from the siege of Leningrad are interesting.¹²

From the Laboratory of Physiological Hygiene, University of Minnesota.

The present review is mainly an abstract of parts of a book, "The Biology of Human Starvation," which will be published by the University of Minnesota Press in 1948. The greatest single source of data is the Minnesota experiment (1944-1946). Both book and experiment are the joint works of Dr. Ancel Keys and Drs. Josef Brozek, Austin Henschel, Olaf Mickelsen and Henry Longstreet Taylor, with assistance on various phases by Miss Angie Mac Sturgeon and Drs. Samuel Wells and Ernst Simonson.

3. EUROPEAN AND ASIATIC FAMINE

The details of the effects of caloric undernutrition are modified by many factors, including particularly the previous state of nutrition, the character of the inadequate diet and the presence of intercurrent disease. In spite of individual and local variations, certain patterns seem to be characteristic of European countries on the one hand and Southeastern Asia on the other.

In the European countries, especially the northern and central regions, food shortages generally result in a diet dominated by whole or undermilled grains (mainly wheat), potatoes, turnips, cabbages and garden vegetables. The result frequently is a diet which is surprisingly good, qualitatively, and deficiencies in vitamins and minerals may not be prominent. The protein content is not vanishingly small and ordinarily comprises something like 10 per cent of the calories.

The diet in Asiatic famine tends to depend on starchy and fibrous foods, which are often exceedingly poor sources of proteins, vitamins and some minerals. The common frequency of endemic infections and infestations in Asia is exaggerated under famine conditions. The combinations of these debilitating conditions are endless, but those which most frequently modify the picture of simple caloric deficiency are hypoproteinemia, anemia, dysentery and deficiencies of some of the vitamins. Famine in Asia is attended by more severe edema and anemia and more frequent neuropathic conditions than in Europe. The present review cannot treat of these complications; it deals primarily with the simpler European type of undernutrition.

4. THE INCIDENCE OF GENERAL UNDERNUTRITION

A large incidence of general undernutrition seems to be an inevitable companion of national poverty, and this is chronically the state of affairs in most of Asia and large sections of Africa. Southeastern Europe, Central and South America. Until recently general undernutrition was frequently the lot of the underprivileged or economically unfortunate classes everywhere; crop failures or economic depression quickly resulted in semistarvation for the poor. In the United States this situation, never very pronounced, seems to have disappeared. In the great depression beginning in 1929 there was little caloric inadequacy and practically no starvation. In this country severe general undernutrition because of inability to obtain food does not exist except by peculiar accident for isolated persons; there is no reason to believe that this situation will change.

This does not mean that there is no general undernutrition in the United States. There are recluses, invalids, children and aged persons who are unable or unwilling to disclose their want and who may be missed by the proper governmental or charitable organization. Probably far more numerous are the persons who are generally undernourished because of the presence of disease. Anorexia of some degree is undoubtedly far more common than indicated by the rare cases diagnosed as anorexia nervosa or Simmonds' disease (hypopituitary cachexia). Undernutrition is prominent in the majority of patients with advanced neoplasms. Temporary undernutrition results from most severe infectious diseases and from major injuries and surgical operations.

The question of the incidence of caloric undernutrition in the general population has been raised by the results of some surveys of dietary intake. On the basis of one or another caloric yardstick, termed proper, ideal, adequate, recommended, optimal or required, comparisons are made with the estimated actual intake;

if the latter value is less than the theoretic standard the case is labeled caloric insufficiency. Thus Wiehl¹³ studied the diets of 1,080 aircraft workers and concluded that "the evidence is strong that a considerable number of these men were below a consumption level believed to be adequate." Further, this author commented on dietary surveys in Toronto, Ontario, and Halifax, Nova Scotia, Canada, to conclude that "it is not unusual for wage earners to eat a diet with less energy than is deemed desirable."¹⁴ The absurdity of conclusions derived from this approach is revealed by data on high school pupils.¹⁵ More than half (55.3 per cent) of these pupils were judged to be calorically undernourished, but analysis of the physical examination data shows that of these undernourished children only 11.1 per cent were underweight while 47.7 per cent of them were overweight by 7.5 per cent or more.¹⁶

5. CALORIC REQUIREMENTS AND RECOMMENDATIONS

The term caloric requirements is widely used, but so far has escaped precise definition, nor will this be attempted here. With any reasonable definition the requirement will be dependent on body size, age, sex, climate, occupation, personal habits, previous state of nutrition and perhaps race.

It is not possible to draw a fine line between caloric adequacy and general undernutrition, least of all by using the caloric intake alone as the criterion. In a given person caloric balance can be maintained over a rather wide range of body weight and caloric intake, and it is not now possible to conclude whether, in the long run, the optimal condition would be toward the upper or lower end of a range amounting to perhaps 10 per cent or more of the average body weight. Changes in body weights are a different matter, and a person not previously obese who loses 10 per cent or more in weight and continues to lose weight is clearly calorically deficient; roughly the same criterion may be applied to the averages for populations.

Various authorities (e.g., the League of Nations and the National Research Council) have made recommendations regarding caloric intake. These are useful in comparing populations and in planning food production; such validity as they have is that of broad averages, and their application to individuals is unwarranted. By and large, the caloric recommendations of the League of Nations and of the National Research Council may be rather higher than optimal. Slight to moderate decreases in per capita consumption below these recommendations in England and Switzerland in World War II and after were associated with evidences of better health. The role of changes in quality of food in these results is obscure, but certainly no adverse effect can be claimed from the caloric reductions. Fleisch¹⁷ concluded that instead of a required average of 2,400 Calories for sedentary adults, the experience of World War II showed an average intake of 2,160 Calories to be sufficient and even beneficial in Switzerland. In the United States careful studies on caloric intake reveal surprisingly low values in some instances where there is no clinical indication of inadequacy.¹⁸

6. FASTING AND ACUTE STARVATION

Both fasting (total abstinence from food) and prolonged undernutrition result in many similar effects such as bradycardia, lowered metabolic rate, hypotension and weakness. But there are also obvious important differences; a few of these may be noted simply to emphasize the point that results in fasting experiments cannot be applied in any detail to problems of chronic undernutrition. Prolonged fasting has its intrinsic scientific interest, but it is rarely encountered in nature.

All reports on fasting are in agreement that the sense of hunger quickly disappears as the fast is continued. If the subject is sedentary, hunger is seldom disturbing after the third day and is usually entirely absent in a week. This loss of hunger is much accelerated by physical work. In experiments in the Laboratory of Physiological Hygiene fasting young men doing hard physical work lost the sensation of hunger in twenty-four hours and incipient nausea, with the attendant revulsion to food, was troublesome on the second or third days. This is in sharp contrast with undernutrition in which the sense of hunger progressively increases until it occupies a major part of the consciousness. Only near the termination with death from starvation does the condition change to resemble that in total fasting. Besides such differences in physical sensation, there are decided tendencies to differences in emotional state. Depression and apathy are almost universally observed in persons with severe undernutrition but in sedentary fasting euphoria and states of excitement are not uncommon.

It may be presumed that fasting is a greater, certainly a more abrupt, emergency and therefore a stronger stimulus to mobilize defense mechanisms in the body. This, together with the simple factor of time, may account for some differences in the blood chemistry compared with that in chronic undernutrition. The concentration of both erythrocytes and leukocytes in the blood of fasting persons tends to remain within relatively normal limits, though subject to variations from time to time. Simple undernutrition, however, tends to produce a leukopenia and a progressive anemia.

Perhaps the most striking differences between total and partial inanition are related to the differences in carbohydrate metabolism. Only a small supply of exogenous carbohydrate (which may be supplied also from exogenous protein) suffices to prevent ketosis. The amount required for this—of the order of 600 Calories per day—is usually obtained even in the worst conditions of famine. In any event, ketosis and ketonuria do not ordinarily appear in chronic undernutrition but pronounced ketosis develops in a few days of fasting. Associated with this difference in respect to ketosis are differences in the respiratory quotient, in acid-base balance and in the blood sugar level.

In the studies in the Laboratory of Physiological Hygiene there were observed interesting differences in the relative resistance of various functions to fasting on the one hand and to prolonged undernutrition on the other. For example, strength, as measured in single maximal exertions, is relatively resistant to fasting but is definitely reduced by prolonged underfeeding. In contrast, the coordination of movements is more strikingly reduced by fasting than by semistarvation.

7. PROTEIN DEFICIENCY AND REQUIREMENTS

Pure protein deficiency, with adequate calories and vitamins, is probably seldom encountered in nature, and little is known about it in man. That it retards or reverses growth and leads to hypoproteinemia and anemia is clear. In Asia it contributes to the picture

of famine edema and probably frequently complicates the decision as to whether there is a major deficiency of calories or thiamine. Protein deficiency will be considered here mainly as it may be associated with general undernutrition or may be confused with it.

Where caloric inadequacy exists the importance of the protein intake is dubious because the protein tends to be used as fuel in place of fat and carbohydrate and thereby is deprived of its ordinary important function. At exceedingly low levels of caloric intake—below 1,000 Calories daily for an adult—the substitution of protein for carbohydrate in the diet has practically no effect on the balance and the net nitrogen loss from the body continues. At higher but still inadequate levels of caloric intake it may be that dietary protein may spare some nitrogen loss, but the evidence is not fully satisfactory.

As in the case of calories, the concept of protein deficiency also involves consideration of protein requirements; presumably deficiency exists when requirements are not met. The situation is more complicated with proteins than with calories because there are several modifying factors. On the other hand, the criteria for establishing protein requirements are, at first glance, simpler and more objective.

In the growing animal it is customary to consider the least amount of protein which will allow the maximal rate of growth to be the requirement. Clearly this is the requirement for maximal growth, but for what else? Whether this level is optimal is an abstruse question which is seldom asked and which, actually, may be unanswerable without more precise definition. Optimal for what? In the case of animals the only values which are readily examined are size and appearance, physical health—meaning merely the absence of disease and defects—and longevity. The latter is infrequently considered, perhaps because the small evidence available points to an inverse correlation between rate of growth and eventual longevity. Numerous factors of great human value which may be affected by the level of protein nutrition are almost never considered, let alone evaluated.

In the adult the usual criterion for the protein requirement is the least intake level which will maintain nitrogen balance. In practice the method is more troublesome than in theory because of the tendency to spontaneous variation and the difficulty of obtaining exact balance. The expedient of measuring nitrogen excretion in fasting or on a protein-free diet is used to get a minimal estimate of the endogenous protein destruction, but this does not tell how much intake of a particular protein or protein mixture will result in nitrogen balance.

- Labile protein reserves (depot nitrogen) in the body are generally considered to be very small, and a sizable negative nitrogen balance for more than a day or two is taken to mean tissue depletion or destruction. But there are situations in which a negative nitrogen balance seems to be physiologic or at least difficult to avoid and perhaps harmless.

8. NITROGEN BALANCE AND PHYSICAL ACTIVITY

Protein catabolism is not increased in muscular exercise; the protein requirement is not altered by participation of protein in the direct energetics of physical activity. This does not mean that the nitrogen balance and requirement are independent of the activity in the long run.

In bed rest, which is the most frequently prescribed therapy in all forms of disease and injury, the nitrogen

balance quickly becomes negative on any ordinary diet and this occurs even in the absence of disease or injury; on the resumption of normal activity the nitrogen balance of the patient becomes positive. This phenomenon would seem to be a kind of disuse atrophy; probably most of the nitrogen lost comes from muscle cytoplasm and there may be no actual cellular destruction, at least at first. Similarly, chronic intensification of activity and muscular exercise calls for increased sarcoplasm and therefore nitrogen retention (exercise hypertrophy). It is puzzling, however, to find that even in bed rest and in the presence of situations that involve destruction of tissue there may be a positive nitrogen balance if the protein intake is forced to extremely high levels.¹⁹ Decreases in hemoglobin and plasma protein may occur in infections even when nitrogen retention is good.^{19a}

Somewhat similar difficulties arise from the fact that a definitely positive nitrogen balance in adults may be induced by some hormones, notably testosterone propionate. It is difficult to avoid the conclusion that the old discussion of protein reserves must be reopened. Since no specific reservoir of labile protein can be found, it may be suspected that the tissue cells in general have some nitrogen reserve and storage capacity.

In any case, the concept of protein requirements seems less simple and precise than might have been hoped. The optimal protein intake may be something else again, but there is little evidence as to quantitative relationships. The recommendations of many authorities, including the League of Nations and the National Research Council, tend to fix on 1 Gm. of protein per kilogram of body weight for adults. But in studies on young men doing hard work in the open no advantage was found for intakes greater than about two-thirds this amount, even when much of the protein was from vegetable sources.²⁰ This tends to be in agreement with recent careful studies on nitrogen balance, in which it was concluded that the National Research Council recommendation for a 70 Kg. man could be reduced to 50 Gm. and still provide approximately 30 per cent margin above requirements.²¹

The conclusions indicated in the preceding paragraph will be challenged by those who believe that neither crude nitrogen balance nor performance in normal health tell the whole story. Large excesses of protein intake have been suggested to be advantageous in building up reserves or antibodies, which may be called on to meet the emergencies of disease or injury. The evidence is still controversial except in the case of persons who have been in negative nitrogen balance and in whom a period of positive balance may be restorative. But elevated protein intakes are not clearly detrimental, though they are expensive, and will undoubtedly be recommended by many nutritionists to be "on the safe side."

9. PROTEIN QUALITY

Long ago animal feeding experiments with different individual proteins demonstrated differences in quality; the protein requirement was different for the several proteins. Some of the vegetable proteins were notably inferior to the animal proteins, and it became customary

to believe that a considerably greater intake of vegetable proteins was required as compared to animal proteins. Some of this difference could be traced to differences in digestibility and absorption, but more important discrepancies were related to metabolic utilization. It is now agreed that the last is dependent on the amino acid composition of the proteins. Inadequacy of one essential amino acid limits the synthesis of the tissue proteins which must contain it and thereby leaves excesses of the other amino acids which are then useless for this purpose. Accordingly, general protein deficiency may result from lack of a single amino acid.

In actual practice, that is, under the great majority of natural conditions, the importance of protein quality is much less than previously supposed. In ordinary diets, even of the vegetarian type, the protein moiety is made up of many different proteins and the chance that all of them will be low in one or more amino acids is small. On diets of limited variety, however, it is possible to have conditions like the earlier rat experiments in which substantially all the protein is supplied by a very few proteins. Such a condition may easily arise in famine areas; in such cases the provision of small amounts of foods rich in the missing amino acids may be highly beneficial.

An example of unsuspected amino acid deficiency and an interrelationship with a vitamin has recently emerged in pellagra. It now appears that pellagra may result from a deficiency in either tryptophane or nicotinic acid and may be successfully treated by either the amino acid or the vitamin.²² This means that the protein requirement may be altered by either its tryptophane content or by the amount of nicotinic acid in the diet. It is entirely possible that other similar relationships between amino acids and vitamins will be discovered. The protein requirement is certainly not an independent entity.

10. THE PROBLEM OF BODY WEIGHT AND FAT ✓

Caloric inadequacy produces a weight loss or a low level of weight for height. In practice, dependence in diagnosis is usually on the height-weight relationship; this means comparison with some set of standards. It is essential to recognize the derivation and limitations of such standards. Since there are as yet neither theoretic nor experimental bases for establishing ideal or optimal relationships between height and weight, recourse is had to averages of supposedly healthy groups which are taken as the standards. The body weight of a given person is then compared with the average of a group of healthy persons of the same sex, age and height. The difference between the individual and the group average is then expressed as pounds overweight or underweight. As an added refinement allowance may be made for body build or type, with standards being broken down into groups such as large frame and small frame. There is no agreement as to how these body types may be properly segregated.

Regardless of refinements of measurements and classification, all these standards involve some major uncertainties. First, the designation healthy in the reference group means only the absence of obvious disease and defect, and all persons in the reference group are presumed to be equally healthy, a presumption without basis and certainly false if it is admitted that health has gradations. Second, it is assumed implicitly that

the average somehow connotes the best; this is a nice democratic arrangement but scarcely scientific.

Presumably, the main concern in all examinations of height and weight is the proportion of the body represented by fat. In very emaciated and in very obese persons the principal difference is in the amount of fat, and this may be roughly gaged by the gross weight. Outside of these extremes, however—and it is precisely with less extreme cases that the real interest lies—the relation of fat to weight is far less exact.

The body fat may be estimated from its specific gravity, taking advantage of the low density of fat.²³ When this is done with a group of ordinary men, with no great extremes of emaciation or obesity, there is no correlation between true fatness and the degree of overweight or underweight calculated from height-weight tables.²⁴

11. WEIGHT LOSS IN UNDERNUTRITION

Reliable data on weight losses in famine and chronic undernutrition are remarkably few. The person who is semistarved against his will almost invariably overestimates his prestarvation weight and his weight loss. The same is often true of persons on reducing diets.

As noted previously, true ideal weights are not known and it is not possible to define precisely the level at which weight loss or departure from standard average becomes important. Probably deviations of less than 10 per cent below standard average weight-for-height are of small moment per se. On the other hand, a sudden weight loss of as much as 5 per cent may be significant. Weight losses of 10 per cent or more that are brought about in a few months in persons not previously obese involve definite impairment in endurance and working capacity and are associated with adverse changes in personality and emotional status.

In previously healthy young adults weight losses up to about 30 per cent can be tolerated with every prospect of eventual full return to normal with proper rehabilitation care. The lethal level is generally around a 40 per cent weight loss, though instances of losses of 50 per cent of weight, with recovery, have been recorded. In severe semistarvation the true weight loss may be difficult to estimate because of the presence of edema; the foregoing figures are for gross weight, including the ordinary amount of edema. When there are exceptionally pronounced edema and ascites, the lethal point may be reached with weight losses of only 20 to 30 per cent.

The rate at which weight is lost in undernutrition is of consequence. In general, it seems that the more rapid the weight loss the more serious is the disability at equal total weight losses. This is a point of both theoretic and practical interest which deserves special study. Allied to this problem is that of adaptive and compensatory phenomena in persons who are habitually underweight in comparison with ordinary standards.

12. MORPHOLOGY: BONES AND TEETH

The bony structures of the body are relatively resistant to caloric undernutrition. No adverse effect on the formed teeth has been objectively demonstrated in either acute or chronic starvation. The bones, however, are

not totally immune from change. Hunger or famine osteopathies have been reported many times in both European and Asiatic persons. Whether the affected individuals are peculiar in one or another respect or may only exhibit a more advanced state of a general tendency is not clear. It is probable that mild degrees of decalcification or other osteopathies are seldom recognized.

Droese²⁵ pointed out the confusion in the literature on the classification of the osteopathies associated with undernutrition but believed that hunger osteoporosis can be distinguished from hunger osteomalacia and late rickets. At the end of World War I a wide variety of osseous disorders were described from Central and Eastern Europe,²⁶ including delayed ossification in young women^{27a} and multiple spontaneous fractures.²⁷ All ages were represented, but the incidence was perhaps highest in elderly women.

In World War II osteopathies again were noted in Europe, the most frequently observed form being that in which there are areas of translucency in the cortex of the long bones and spontaneous fractures at points of mechanical strain.²⁸ Pompen and associates^{28b} described 24 cases of what they called "hunger osteopathy." They stated that in all cases the diet had been deficient in calcium, phosphorus, protein and vitamin D, and many of the patients had been indoors for long periods. Though undernourished, these patients were not really starved. This situation is radically different from that of the American prisoners of war in Japanese prison camps who showed roentgenologic evidence of osteoporosis on repatriation; these persons had ample exposure to the sun and frequently ate ground fish bones in prison.²⁹ Such evidence does not support a belief that either calcium or vitamin D deficiency is essential to the development of hunger osteopathy.

In the Minnesota experiment bone density was studied by Dr. Pauline Berry Mack with elaborate quantitative methods developed at Pennsylvania State College. Evidence of any abnormality in bone density was not seen. It seems probable that hunger osteopathies tend to develop only when the undernutrition is prolonged (for a year or more), and even then there must be other factors operative because the incidence never seems to be exceedingly high in famine populations.

13. MORPHOLOGY: MUSCULAR TISSUES

Muscular wasting is always a prominent feature of severe undernutrition. Experimental studies on animals indicate that, in general, the percentage weight loss of the voluntary muscles is somewhat greater than percentage weight loss of the entire body. Most of this wasting seems to be a result of shrinkage of the individual muscle fibers, but in late stages actual destruction of the cells may occur (Jackson,⁶ page 162). Brown atrophy, loss of cross striations and granular degeneration have been described, as well as a reduction in the liposomes (minute fat droplets) and occasional appearance of vacuoles.

Presumably, moderate undernutrition only affects

the mass of sarcoplasm, at least for a time, and full recovery on refeeding should be possible. With more severe starvation, where muscle cells are undergoing actual destruction, it may be thought that full recovery could be brought about only by relative hypertrophy of the remaining intact muscle cells. However, mitoses in skeletal muscle of adult animals have been reported during ample feeding following starvation.³⁰

Contrary to the textbooks, heart muscle behaves much like skeletal muscle in starvation. In both acute and chronic undernutrition the heart shrinks in volume and in weight, the loss being nearly in proportion to the total weight loss of the body.³¹ In the Minnesota experiment the average gross volume of the heart, at systole, measured from teleroentgenkymograms, decreased 17 per cent when the body weight decreased 24 per cent. Since the starved heart may well eject its blood less completely than the normal heart, the actual tissue loss may be underestimated by this roentgenologic method, but in animals the weight loss of the heart is generally a trifle less than proportionate to the total weight loss.

The position of the heart in the chest is also changed in starvation so that ordinary linear measurements do not give an exact indication of the change in total size. In the Minnesota experiment the major axis of the heart in the standing position was, on the average, 4.4 degrees more vertical in starvation than in the control period.

14. MORPHOLOGY: BRAIN AND NERVOUS TISSUE

It has long been taught that the brain and the heart are somehow "protected" in starvation, so that they do not shrink and waste as do the other soft tissues of the body. In the case of the heart, as has been noted this view is in error. But all evidence is in agreement that the brain, and nervous tissue generally, loses little weight even in severe starvation. This does not necessarily mean, however, that these tissues are really unaffected by undernutrition. Histologic examination reveals atrophy, cloudy swelling, chromatolysis and a variety of degenerative changes in the cells.³² The explanation of the apparent paradox may be suggested by the general agreement that vacuoles and evidences of edema appear in the nervous tissue. Presumably the weight changes are limited because the gross structure is preserved with replacement of cytoplasm, or even of cells, by water. The changes in the spinal cord are similar to those in the brain and may be even more pronounced in the anterior horn cells.³³ Nor are the peripheral nerves immune to the effects of starvation, though the medullated fibers are only slightly affected, morphologically.⁶

15. SKIN, HAIR AND EYES

Caloric deficiency of more than slight degree tends to produce characteristic changes in the skin and hair, but these are not the same in all cases. The skin becomes thin, dry, and grayish. It is cold and "dead" to the touch and tends to slight cyanosis in cold weather. The appearance suggests old age. Besides these changes, which are generally seen and were striking in the men in the Minnesota experiment, there are other changes which appear with less regularity.

A substantial proportion of persons subsisting on a European type of famine diet exhibit rough gooseflesh-

like areas of skin, most often on the extensor surfaces of the thighs and upper arms. The condition resembles the follicular hyperkeratitis and folliculosis sometimes associated with vitamin A deficiency. The causation is puzzling because its incidence is highly variable and does not seem to be clearly related to the state of vitamin A nutrition.³⁴ This condition did not appear in the inmates of Japanese prison camps in spite of gross dietary deficiencies.³⁵

A remarkable peculiarity of the skin in starvation has escaped serious attention until recently. A splotchy, dirty brownish pigmentation, appearing anywhere on the body but most often seen on the face, was casually mentioned in some old reports on undernutrition but occasioned much surprise when it was frequently seen at the close of World War II.³⁶ Most of the Minnesota men exhibited it to some degree. The mechanism of the production of this famine pigmentation is unknown; it is not related to nicotinic acid deficiency or pellagra.

The hair in starvation is usually dry, dull and starting. There are many impressions that hair almost ceases to grow and tends to fall out, but objective evidence is lacking.

There is a characteristic appearance of the eyes in starved persons. They look dull and dead. On closer inspection it is seen that the sclera and cornea are unusually devoid of blood vessels so that the whites of the eyes resemble unglazed porcelain. In the Minnesota experiment men even soap solution failed to produce reddening.

16. MORPHOLOGY: BLOOD VOLUME

With the exception of bone and nervous tissues, the formed tissues of the body generally are decidedly diminished in gross bulk in undernutrition. In some respects it is proper to consider the blood as a tissue, and its behavior in comparison with other tissues is of interest. More particularly, it is essential to allow for changes in the gross mass of the blood before evaluating the true meaning of changes in the concentration of the formed elements.

Measurements of the blood volume in relation to the nutritional state are still few in number, and some limitations in the technical methods restrict the conclusions which may be drawn from the data. All present methods refer only to the circulating blood. Although in man the reservoirs of noncirculating blood are small, it is possible that the situation may not be precisely the same in normal and in starved persons. Moreover, when starved and normal persons are compared there is the question as to how the blood volume should be expressed to allow properly for differences in gross body size.

Plasma volume was estimated in 15 inmates of the Belsen concentration camp who had lost something like 30 or 35 per cent of their body weight.³⁶ In the Minnesota experiment the plasma volume was studied systematically before, during and after starvation.³⁶ As far as they go, the Belsen data confirm the Minnesota work. Before starvation the Minnesota subjects had an average plasma volume of 3.15 liters, and this amounted to 45.3 cc. per kilogram of body weight. At the end of six months of semistarvation the absolute

plasma volume had increased slightly to an average of 3.41 liters, but this then represented 59.3 cc. per kilogram of the total body weight.

The absolute plasma volume, then, tends to remain constant or increases slightly in starvation. The associated anemia means that the total circulating blood volume is somewhat reduced, but in proportion to the body weight there is a definite blood plethora. These changes are slowly reversed in subsequent rehabilitation; the Minnesota men were fully restored in this respect in about three months.

The behavior of the blood volume in the terminal stages of the most severe starvation may be more complex. Some famine victims die in obvious shock with all signs of severe dehydration; the persistent diarrhea often seen in these cases may produce dehydration, sharp reduction in blood volume and shock as in cholera.

17. MORPHOLOGY: BLOOD CELLS

Some degree of anemia is invariably observed in persons who have undergone prolonged semistarvation. In Asia severe anemia is frequently seen in such persons, but this is probably mainly a reflection of the effect of malaria and other blood-destructive conditions.

In the Minnesota experiment the diet, like European famine diets, was not deficient in iron but there was a progressive moderate anemia in every man during semistarvation. Beginning with an average of 15.1 ± 0.88 Gm. per hundred cubic centimeters of blood in the control period, the average value declined to 12.6 ± 0.80 Gm. after 12 weeks of semistarvation (15 per cent weight loss) and to 11.7 ± 0.80 Gm. at 24 weeks when the weight loss was 24 per cent.³⁸ These changes are comparable to many observations in famine areas in Europe.

In general, the erythrocyte count and the hematocrit reading change as does the hemoglobin concentration, but the parallelism is not exact. The red blood cells tend to become slightly larger in starvation; the anemia is of the macrocytic type. In the Minnesota experiment the average volume of the red cell, and the content of hemoglobin in it, had increased about 7 per cent at the end of semistarvation.

From the data on plasma volume, the hematocrit reading and the hemoglobin concentration, the total circulating hemoglobin can be calculated. In starvation this is decreased, the decrease in the Minnesota experiment being almost exactly in proportion to the decrease in gross body weight.³⁹

The cause of the anemia in undernutrition is not clear; iron deficiency is not primarily responsible. Sternal marrow examinations so far have not provided the answer. Increased, decreased and normal degrees of erythropoiesis have been found in the marrows of anemic starving persons. The possibility that excessive peripheral destruction of the red blood cells is involved is suggested by reports of hemosiderin deposits in the tissue.³⁷

In comparison with the rather large variability of leukocytes in normal subjects, the changes in starvation are ordinarily not dramatic. A definite but moderate leukopenia is the rule except where there is intercurrent infection. In the Minnesota experiment the mean leukocyte count was 6,346 per cubic millimeter in the control period and at the end of semistarvation it was 4,129, a decline of 34.9 per cent (see also Zimmer⁴⁰).

Correcting for the change in total blood volume, the decrease in total circulating leukocytes averaged 24.1 per cent.

The composition of the leukocytes by types in semistarvation and in fasting has been reported many times in the older literature, but no consistent picture emerges. Several workers found an apparent relative lymphocytosis,³⁸ but this was not observed in the Minnesota experiment.

In rehabilitation following prolonged undernutrition the correction of the anemia takes place slowly even when protein and iron are supplied in abundance. In the Minnesota experiment the hemoglobin concentration only recovered slightly in 12 weeks and was still appreciably below the control values at 20 weeks when the body weight had been regained; 3 months later, however, (i.e., a total of 8 months after the end of semistarvation), the blood was normal.

18. THE GASTROINTESTINAL TRACT

Gastrointestinal disorders are almost invariably reported from famine areas and frequently contribute greatly to the disability and death of famine victims. Diarrhea and dysentery are always major factors in famine mortality in India,³⁹ and were prevalent in Europe in both World Wars.⁴⁰ The majority of internees and prisoners of war in the Japanese camps in World War II suffered from diarrhea.³⁹ In such situations, however, there is a breakdown of sanitation or recourse to strange and peculiar materials as food, or both, so that it is impossible to assess the effects of undernutrition as such.

Attempts to isolate specific pathogens from the stools in most of these cases have been conspicuously unsuccessful. If organisms in the intestine are responsible it must be concluded that forms which normally are not pathogenic may interfere with the function of the intestine of the starving man. Famine victims usually eat anything and everything they can get, and this often means the consumption of irritating, indigestible and spoiled foods, so that nonspecific diarrhea would not be surprising except for its severity.

In the Minnesota experiment, in which strict sanitation was maintained and bad or questionable items of food were never used, diarrhea did not occur at any time though the degree of starvation was comparable to that in the field where diarrhea is so pronounced. This would seem to prove that starvation alone is not causative.

Extreme pathologic changes are often found in the intestinal mucosa of famine victims. These changes may explain the diarrhea in a sense, but the tissue changes are probably the resultant of several factors, of which caloric undernutrition is only one. Certainly starvation produces degenerative changes in all the tissues of the gastrointestinal tract as elsewhere in the body. Additional insult may then easily produce a variety of disorders. An increase in peptic ulcer is commonly noted in periods of undernutrition.⁴¹

The course of the digestion as affected by starvation is an important question in devising relief programs. In the spring of 1945 it was at first thought that many

famine victims in Europe would require intravenous alimentation, but this proved undesirable in trials in the Netherlands and later in the Belsen concentration camp. Frequent feedings of easily digested foods usually bring about rapid improvement; when this is not the case even the most careful intravenous management may be unsuccessful. The critical point may be indicated by dysphagia. If the patient still feels the pangs of hunger and wants to eat, even a rough and ready feeding program with plain foods will suffice; if the appetite is gone the prognosis is bad (except in anorexia nervosa).

In the Minnesota experiment there were few indications of digestive impairment and no complaints on this score. Gastric acidity (fasting and after histamine) was substantially normal. Gastric motility (rate of evacuation of a test meal) was slightly but consistently depressed.

19. THE BASAL METABOLIC RATE

The basal metabolic rate always represents a large fraction of the total metabolism so that its relation to the caloric intake is a major determinant in the caloric balance. Under normal conditions the basal metabolic rate of the individual is relatively fixed and differences between persons of the same age and sex are considered to be dependent on body size and on the activity of the thyroid gland. It is generally believed that habitual differences in food intake and relative obesity in normal persons have little or no effect on the basal metabolic rate. Persons who are habitually thin, even to a decided degree, apparently have a normal basal metabolic rate when this is expressed per unit of body surface.⁴²

When the food intake is sharply reduced below the habitual level for the subject the basal oxygen consumption promptly declines, and this alteration tends to be progressive if the inadequate diet is continued: the absolute change is large. The 32 men in the Minnesota experiment had an average basal consumption of 229 cc. per minute before starvation. After 12 weeks of the famine diet, when the body weight had fallen 15 per cent, this had decreased to 155 cc. and after 24 weeks the average was 139 cc. per minute; a loss of 24 per cent in body weight was associated with a drop of 39 per cent in the basal oxygen consumption. These data, which extend and confirm earlier results, are of obvious practical significance. When subsistence is maintained at a calorically deficient level the progress of the undernutrition itself progressively decreases the caloric deficit so that there is a tendency toward adaptation or compensation.

The absolute changes in the basal metabolism raise questions about the mechanisms involved and the intensity and character of the metabolic processes in the metabolizing tissues. These changes are not merely a reflection of changes in the body surface which would be predicted from the so-called surface law. In the Minnesota experiment, for example, there was an average drop of 28 per cent in the oxygen consumption per square meter of body surface. Subnormal values for the basal metabolic rate, expressed in units of body surface, are universally found in famine areas.

Analysis of these data suggests the need for renewed scrutiny of the surface law. As the body shrinks in starvation the surface increases relative to the tissue mass so that, other things being equal, there would

be a greater heat loss and a lower point of temperature equilibrium. The lowered body temperature in turn would retard the enzymatic processes which constitute the metabolism. Although such a chain of events undoubtedly operates, it is not possible to explain the total metabolic alterations on this basis. The decline in body temperature is exceedingly small; in the Minnesota experiment it fell less than 1 degree (F.) in 24 weeks. As a matter of fact, the theory of a heat exchange basis for the surface law is no longer seriously entertained. Changes in peripheral blood circulation readily control the body temperature in the face of great changes in heat production and external temperature.

An important problem is the behavior of the metabolic rate per unit of metabolizing tissue. A first approximation is obtained by expressing the metabolic rate in relation to gross body weight. In the Minnesota experiment the basal oxygen consumption per kilogram of body weight declined 15 per cent in semistarvation. But the gross body weight is not necessarily a reliable index of metabolizing tissue. Fat, bone mineral and extracellular water clearly have little or no metabolic activity. In starvation the proportional composition of the body is changed, there being a relative reduction in fat and relative increases in bone mineral and extracellular water. When allowance is made for these differences, which is possible with the Minnesota data, the apparent alteration in metabolic intensity is reduced but the values are still about 10 per cent below the pre-starvation control. In other words, prolonged severe undernutrition produces a small but seemingly significant drop in the basal metabolic rate per unit weight of active tissue (body weight less weights of fat, bone mineral and extracellular water).

In rehabilitation following undernutrition the basal metabolic rate rises more or less parallel to the dietary intake and the gain in body weight. Before body weight is fully restored, however, and for some weeks or months thereafter, the basal metabolic rate surpasses the value which was characteristic of the subject in the prestarvation state. This is particularly clear when the basal metabolic rate is expressed per unit of active tissue or per unit of body weight less fat. In the latter terms the average for the men in the Minnesota experiment after 20 weeks of refeeding, when body weight had been restored, was 13 per cent above their own normal metabolic rates.

20. TOTAL ENERGY METABOLISM

The total energy metabolism is made up of the basal metabolic rate, the specific dynamic action (some 10 per cent of the basal metabolic rate), and the cost of muscular movement and tonus in excess of the basal state. In starvation or severe undernutrition the basal metabolic rate is sharply diminished, as previously noted. Presumably there is also a proportional reduction in the specific dynamic action. The other items in the total metabolic picture are also much reduced.

The energetic efficiency of muscular activity is substantially unaltered in undernutrition except in the most extreme states where gross incoordination may interfere. The energy cost per kilogrammeter of external work like walking and bicycle riding is practically unaltered. This simplifies the analysis.

A large part of the energy cost of muscular work is entailed by moving the body or its parts. In locomotion the work done is simply proportional to the body weight. It follows, then, that the metabolic cost of muscular work is reduced in starvation because of the

42. Blunt, K.; Nelson, A., and Oleson, H. C.: The Basal Metabolism of Underweight Children, *J. Biol. Chem.*, 49: 247-262, 1921. Strang, J. M.; McCluggage, H. B., and Brownlee, M. A.: Metabolism in Undernutrition: Its Changes During Treatment by High Caloric Diet, *Arch. Int. Med.* 55: 958-978 (June) 1935.

reduction in weight of the body and its movable parts. For the majority of activities the reduction in work energy may be considered roughly proportional to the loss in body weight.

Perhaps even more important in most natural life situations is the fact that voluntary activity is greatly diminished in severe undernutrition. Energy expenditure is automatically curtailed and the starving man tends to be immobile, to move slowly when movement is necessary and to assume postures which are most conservative of energy.

The combined effect of all these factors is a large reduction in energy expenditure. In the Minnesota experiment the daily total energy expenditure at the end of semistarvation was only about half that in the control period, in spite of the fact that a fixed occupational and exercise program was maintained throughout. In severe natural famine the reduction in energy expenditure may be considerably greater, so that caloric balance may be achieved at surprisingly low figures. The caloric deficit is apt to be grossly overestimated when calculated simply from caloric intakes.

During nutritional rehabilitation the return of a sense of well-being is coupled with an increase in voluntary physical activity, but the habit of energy conservation is not quickly broken. An effort of will or coercion is often necessary to promote recovery in physical fitness by exercise. The total daily metabolism tends to lag behind the proportional change in the basal metabolic rate in recovery.

21. THE CARDIOVASCULAR SYSTEM

The response of the cardiac musculature to undernutrition has been mentioned in section 13. Changes in cardiac and circulatory function are obvious and in some respects more dramatic.⁴¹ It is well known that both total fasting and prolonged undernutrition tend to produce bradycardia and hypotension in rest. The significance of these changes and other details of circulatory function have received little attention until recently.

Starvation bradycardia is obvious in all instances except where there are extremely powerful heart-accelerating forces at work, such as systemic infection, great excitement or fear, or impending circulatory collapse. From the literature the impression is gained that the bradycardia is perhaps most profound in the earlier stages of severe undernutrition; certainly the degree of bradycardia is not simply related to weight loss. This was also indicated in the Minnesota experiment where the subjects' average basal pulse rate of 34.9 per minute after 12 weeks rose to 37.8 after 24 weeks of semistarvation.

The contrast with beri-beri heart is important. In beri-beri, there may be resting bradycardia but small physical exertion produces decided tachycardia. In simple starvation, exercise produces an increase in the heart rate but this is not disproportionate to the resting rate.

The bradycardia of starvation does not involve heart block; the rhythm is of the sinus type.⁴² The rhythm is remarkable for its great regularity; the variability of the length of the P-R interval is smaller than normal in both absolute and relative terms. The electrocardiogram in a state of severe undernutrition shows peculiarities in almost every item of measurement,^{43b} but the amplitude changes are most striking. The voltages of

all deflections are reduced, particularly the P waves and the QRS complex.

Both systolic and diastolic blood pressures are reduced by undernutrition but these changes, unlike the bradycardia, are moderate and progressive. In severe chronic undernutrition the systolic blood pressure is generally reduced 10 to 30 mm., with a smaller drop in diastolic pressure; the pulse pressure is invariably narrower.⁴¹ These changes have interesting relations to problems of hypertension.⁴⁴

The total circulatory function in starvation is, superficially at least, well preserved. Though there is a tendency to slight peripheral cyanosis, there are usually no complaints referred to the heart and no signs of impending or actual failure except in the terminal state. Nevertheless, detailed analysis indicates that the margin of safety is reduced and that the rate of circulation per unit of metabolic rate is substantially lowered.⁴¹

In starvation it is common to observe fainting and giddiness, particularly in the upright posture. It is surprising, therefore, to note that no inadequacy of circulatory adjustment to posture is revealed by tilt-table tests.⁴⁵

The restoration of cardiocirculatory function to normal by refeeding does not necessarily follow a simple path of reversal of the starvation changes. When the rehabilitation diet is abundant there may appear signs of relative cardiac insufficiency at the time when the rate of gain of weight and of the basal metabolic rate are at their peaks. The pulse rate, in both rest and exercise, and the venous pressure tend to exceed normal control values, and even frank congestive failure may intervene.⁴¹ The sudden rise in the basal metabolic rate in rehabilitation may produce an intolerable strain on the heart. Full restoration of the heart is not as readily achieved as is the body weight.

22. STRENGTH AND COORDINATION

All psychomotor functions deteriorate in caloric deficiency, and the result is a serious impairment in working capacity. Simple muscular strength, as measured in a single maximal exertion, declines steadily but not as dramatically as does the capacity for continued muscular exertions (endurance). In the Minnesota experiment the single-effort strength of hands, arms and back declined about 30 per cent and the endurance in severe work which produces exhaustion in a few minutes fell as much as 85 per cent. Collapse in the latter tests appeared to be due to muscular failure instead of the circulatory-respiratory type seen in normal persons.

Neuromuscular coordination is impaired by caloric undernutrition, but the relative deterioration is less than in purely muscular capacity.

The psychomotor functions are only slowly restored by refeeding. When the body weight has been regained, there may still persist a serious reduction in muscular endurance. In young men full recovery in these respects takes the better part of a year.

23. THE SPECIAL SENSES

Simple caloric starvation seems to have no deleterious effects on the special senses. In the Minnesota experiment visual acuity was unaffected and there was no evidence of alteration in the senses of touch, taste and smell. Auditory acuity is ordinarily slightly improved

at all frequencies; this was clearly demonstrated in the Minnesota subjects and is confirmed by less objective methods from famine areas. The cause of the sharpened hearing may be mechanical, associated with an enlargement of the free space in the auditory canal. The improvement in hearing is lost during nutritional rehabilitation.

24. INTELLECTIVE FUNCTIONS

Starving persons are ordinarily averse to any effort, including that of the intellect, and their preoccupation with food and their own plight may give an impression of stupidity or mental incapacity. Actually, however, there is no evidence for a decline in basic intellectual capacity. In the Minnesota experiment exhaustive studies on memory, reasoning power, verbal and arithmetical facility, and so on, revealed no changes in spite of the subjective impression of most of the men that their mental powers had been reduced.

25. PERSONALITY AND EMOTION

Severe caloric inadequacy produces profound changes in the personality and the subjective state.⁴⁶ Externally, the major characteristics are apathy, depression and introversion. Social contacts are avoided and sex interest declines sharply. Psychiatric methods reveal, besides the depression, a well defined rise in the tendencies to hypochondriasis and hysteria. Though the behavior is almost never aggressive, it is easy to discern a tendency to a heightened irritability. The behavior which would ordinarily be associated with increased irritability is suppressed by the overwhelming physical lethargy.

It is difficult to appreciate the enormous preoccupation of the starving man with food and eating. His thoughts tend to be exclusively dominated with these concerns. Their expression may range from constant day-dreaming about eating to extensions such as interest in scientific agriculture. Niceties of behavior are brushed aside where they interfere with the full expression of these interests. Even when the food supply is restored the concern about food persists for many months; a common expression is food hoarding, even when there is not the slightest reasonable basis for this.

Emotional crises and seriously disturbed behavior may arise from the conflict between the concentration on food and previously fixed convictions.^{46b} While these may result in irritated or antisocial behavior or even lead to self-destructive impulses, they do not partake of the character of the true psychoses.

Personality changes in refeeding may be even more complex; certainly the behavior may be more variable. As the physical state improves the tendencies toward depression and hypochondriasis diminish, but they may be returned in force by disappointment in the rate of recovery or threats of renewed food restrictions. The return of physical vigor allows outward manifestation of formerly suppressed irritability. At this stage these persons are far more difficult to manage and maintain in an orderly social structure than when they were physically deteriorating. These facts obviously have great sociologic importance.

26. UNDERNUTRITION AND RESISTANCE TO INFECTION

There is no aspect of undernutrition about which there is a more fixed common belief—and less objective evidence—than the question of the effect on resistance to infection. The historical association of famine and pestilence has been so uncritically accepted as indicat-

ing cause and effect that there is a dearth of actual research and analysis. The whole problem of nutrition and infection is enormously complicated;⁴⁷ obviously no broad generalizations are possible.

Properly, each infectious disease should be considered separately. However, only in the case of tuberculosis is there an appreciable amount of acceptable information. Tuberculosis is discussed separately (section 27); here the other problems are noted briefly. The evidence, such as it is, concerns: (1) indirect suggestions from antibody titers, precipitins, gamma globulin and the like; (2) animal experiments involving experimental infection; (3) casual observations on natural infections in animals; (4) clinical reports, and (5) morbidity and mortality data from famine areas.

A long series of papers from Dr. Paul Cannon's laboratory has stressed the importance of nutrition, particularly protein nutrition, in antibody formation.⁴⁸ Most of these animal experiments involved both severe caloric and protein deficiencies, the latter being more drastic than usually seen even in severe famine. The exact relevance of these observations to human caloric deficiency is uncertain; the data themselves are contrary to some older studies.⁴⁹

Experimental studies with injections of micro-organisms into animals in various states of nutrition have been few and of indifferent quality. Opposing observations make it clear that no general conclusions are possible so far (e.g., Edwards⁵⁰ versus Robertson and Tisdall⁵¹). Reports on the incidence and course of natural infections in underfed animals are similarly at variance.⁵²

Clinical records may be used to support or to oppose the claim that caloric deficiency, per se, produces a decreased resistance to infection. Some interesting recent data have to do with clinical experience in hospitals associated with prison camps in World War II where surgical procedures were often performed on persons in a deplorable nutritional state without unusual complications.⁵³

Morbidity and mortality records from World War II provide material for thought. In contradistinction to previous wars, pestilence was never rampant except where sanitation control was neglected. No epidemics appeared in Western Holland or Greece at the times when there was mass starvation in those areas. The diphtheria epidemic of 1946 appeared to affect the American occupation troops just as severely as the underfed populace. Markowski⁵⁴ stated that typhus mortality was worse among the German guards than among the starving Russian prisoners at Hammerstein.

On the whole, the evidence to date suggests that there are various relations in different animals and with different organisms, that the old association of famine and pestilence was largely due to sanitary faults and that in man caloric deficiency is not necessarily productive of a lowered resistance or a heightened susceptibility to infectious diseases in general.

27. TUBERCULOSIS

As far into the past as there are records it is clear that tuberculosis has always increased in periods of severe food restriction. The evidence for the period of the first World War is particularly valuable because it is possible in some cases to dissociate the factor of food shortage from those of overcrowding, excessive labor, sanitation and medical care. The data from Germany⁵⁵ are useful, but the analysis of Faber⁵⁶ for the situation in Denmark is most significant.

Denmark's domestic food consumption in World War I decreased and then increased owing to the blockade. The housing situation became extremely bad after the food supply was maintained at a good level. Medical care was well maintained at all times. Sharp changes in tuberculosis mortality were closely related to the level of food consumption and were relatively independent of overcrowding, unemployment and the like.

The data from World War II are adding much confirmation to the conclusion that tuberculosis morbidity and mortality are increased by caloric deficiency.⁵⁷ In some cases changes in ascertainment distort the figures,⁴¹ but the general picture is convincing. Clinical reports from areas of food shortages emphasize the frequency of a fulminating type of the disease. Tuberculosis is certainly a most serious problem under any circumstance when there is a prolonged severe food shortage.

28. UNDERNUTRITION AND NEOPLASTIC DISEASES

It is now well known that the incidence, growth and recurrence of several types of tumors in animals can be reduced or even prevented by exceedingly severe undernutrition.⁵⁸ The prophylactic and therapeutic possibilities of caloric restriction in man have been argued,⁵⁹ but there are serious difficulties in application. In animal experiments inhibition of tumors has required the use of dietary levels so low as to retard growth greatly and to prevent estrus.⁶⁰ While such levels are reached in human famine, there are no data to show any important effect on the incidence or course of cancer in man. The most that may be said is that the mortality statistics from starvation periods (e.g., in Greece and the Netherlands) do not indicate any increase in cancer; the number of deaths ascribed to neoplasms is reduced in proportion to the total deaths.⁴¹

29. HYPERTENSION AND CORONARY DISEASE

It has been noted (section 21) that caloric undernutrition normally produces a fall in the blood pressure. What effect this may have on the incidence and course of hypertension and vascular diseases in general is an

intriguing question. There are many clinical impressions which are suggestive, but these have little objective basis. Mortality data from famine areas are of limited value because of the problems of certification; in most cases the figures are only grouped under such broad headings as "cardiovascular disease."

The hospital records of Leningrad during the siege of 1941-1942 and after are interesting. In this period of severe food shortage the hospital admissions for hypertension remained at about the ordinary level but the deaths from such conditions dropped sharply.⁶¹ After the food supply was restored to much better levels there was a veritable epidemic of hypertension and coronary deaths in Leningrad. Transient hypertension during refueling was also noted in the Far East.⁶² There is clearly an important area for research here.

30. UNDERNUTRITION AND DIABETES

The association of diabetes with obesity and the advantage of food restriction in this disease are well established.⁶² These general relations are reflected in substantial changes in morbidity and mortality from diabetes during periods of food shortages even when these are not productive of real starvation.⁶³ An improvement in the clinical condition of patients with established diabetes is quickly apparent when the food supply is restricted. Beckert⁶⁴ compared 604 diabetic persons in Dresden in the summer of 1939 and again in the summer of 1940. A loss in weight was recorded in 62.2 per cent. Clinically, 45 per cent were improved and only 5 per cent were worse. In Belgium, moderate food shortages in the first three years of World War II were associated with a notable diminution in diabetes morbidity and a more favorable clinical course of this disease.⁶⁵

31. FAMINE EDEMA

Famine (hunger or war) edema was in a sense "discovered" in World War I, though it had been casually observed throughout the ages. The simulation of this condition by protein depletion and a variety of evidences supporting Starling's theory of the role of colloid osmotic pressure in fluid balance led to almost universal belief, in spite of unheeded objections,⁶⁶ that famine edema is simply a result of hypoproteinemia. World War II, however, contributed an unexpected denouement.⁶⁷

In starved persons edema may appear with relatively normal values for plasma protein concentration and the albumin fraction is not necessarily decreased. Furthermore, though on the average there may be some relation between the plasma protein level and the extent of the edema, the relation is extremely rough and does not hold for individuals.⁶⁸ Cardiac failure is not involved, and the venous blood pressure is actually lower than normal. Finally, it should be noted that the edema fluid is extraordinarily low in protein.

In ordinary cases of edema due to famine the edema is not so much an accumulation of tissue fluid as simply a retention of the prestarvation level of extracellular fluid; the edema tends to be the expression of a relative and not an absolute excess of fluid in the body. It is probable that mechanical factors—elasticity and structure—outside the capillaries are responsible.

The edema is ordinarily only moderate and is of the soft, dependent type, being notable in the face in the morning and shifting to the lower extremities during the day. Ascites is seldom seen except where there is severe anemia, intercurrent infection, heart failure or decided hypoproteinemia. The latter appears when the diet is unusually devoid of protein. The edema itself is not particularly troublesome, but it is a useful rough guide in evaluating the nutritional state in surveys; it is not a reliable or sensitive indicator in the individual. During refeeding it tends to appear and disappear, being affected by exercise and posture as well as the dietary level.

32. PROBLEMS OF REHABILITATION

The problems of nutritional rehabilitation following semistarvation periodically arise in acute form. The practical necessities of relief allow scant opportunity for research, and the factual information is extremely little. In large scale relief operations the limitations of food materials emphasize the distinction between optimal and feasible programs; the criteria must be those of efficiency and economy.

The character of the diet in the preceding period of semistarvation is important. In general, there are vitamin deficiencies to be corrected in Asia whereas in Europe these tend to be much less prominent. The severity of the state of undernutrition is a determining factor. Almost any food items may be used for the majority of an underfed population, but those persons in an extremely depleted state need easily digested food in frequent feedings. Intravenous feeding is seldom desirable or necessary.

Experience in Europe supports the observations in the Minnesota experiment where it appeared that calories in relative abundance are the first need. The Minnesota subjects manifested a rate of recovery closely proportional to the calories supplied; at intakes of less than 2,700 Calories daily, recovery was exceedingly slow and apparently would have required more than a year. In the Minnesota experiment it was found that intakes over 5,000 Calories daily are unnecessary and may be dangerous. In these young men engaged in light activity the optimal level appeared to be something like 3,500 Calories.

With adequate calories supplied in ordinary foods, including breads made with low-extraction flour, the protein intake will normally be 70 Gm. or more per day. At these levels the isocaloric substitution of protein for carbohydrate produced no discernible benefit in the Minnesota experiment. The extra protein supplement was limited to only 20 Gm. a day, but there is no reason to believe that larger amounts would have important effects.

Special vitamin supplements had no effect on the course of rehabilitation in the Minnesota experiment, nor is there any objective evidence of value in the trials in Europe. It is unnecessary to supply vitamin concentrates unless there is clinical evidence of vitamin deficiency and the relief diet itself is a poor source of vitamins.

With the best of diets and rehabilitation treatment, full recovery from severe undernutrition is slow. Body

weight is regained long before functional normality is restored. When the undernutrition lasts for many months and the weight loss is between 20 and 30 per cent, it is probable that complete rehabilitation, including restoration of working capacity, is seldom achieved in less than a year in young adults. With older persons a slower recovery must be expected. It is possible that children recover more promptly.

33. LESSONS FROM CONTEMPORARY FAMINE EXPERIENCE

Acute and persistent problems of starvation and food shortages began to be apparent early in World War II. The problems were not new, but their overwhelming nature has focused attention on them so that it should no longer be possible for them to be neglected by nutritionists in favor of the spectacular advances concerning individual nutrients. But this reawakened interest is coming late, so late that years of opportunity for definitive research have been lost. The data gathered in and immediately after World War II are valuable, but they barely touch many points and on others leave confusion and uncertainty.

Many of the accomplishments and the problems recognized but unanswered are indicated in several recent discussions and monographs.⁶⁹ These may be examined with profit not only for the facts presented but for the indications of facts not collected, the theories not critically examined and the questions not answered.

ACCEPTED FOOD

The following products have been accepted as conforming to the Rules of the Council.

JAMES R. WILSON, M.D., Secretary.

Vital Foods Corporation, Evanson, Ill. (Distributed by the American Hospital Supply Company, Evanston, Ill.)

TOMAC ORAL PROTEIN SUPPLEMENT, UNFLAVORED, consists of Ca-Sal (casein and lactalbumin), food yeast, lactalbumin, carrageenin and salt. *Analysis* (submitted by manufacturer).—Protein (N $\times$ 6.25) 67.5%, carbohydrate 16.5%, ash 7.0%, moisture 6.0%, ether extractables 1.0%. *Calories*.—3.25 per gram; 92 per ounce.

Use.—For conditions that require an increased intake of protein.

TOMAC ORAL PROTEIN SUPPLEMENT, FLAVORED, consists of Ca-Sal (casein and lactalbumin), lactalbumin, food yeast, sugar cane, carrageenin and flavor.

Flavoring.—Imitation powdered maple flavor, or pure lemon flavor with citric acid.

Analysis (submitted by manufacturer).—Protein (N $\times$ 6.25) 61.5%, carbohydrate 26.5%, ash 6.2%, moisture 5.1% and ether extractables 0.7%. *Calories*.—3.25 per gram; 92 per ounce.

Use.—For conditions that require an increased intake of protein.

Sharp & Dohme, Incorporated, Glenolden, Pa.

"DELCO" PROTEIN-CARBOHYDRATE GRANULES, mixture of protein and carbohydrate, with vanillin, coumarin and essential oils as flavoring agents.

Analysis (submitted by manufacturer).—Protein (N $\times$ 6.25) derived from milk 50 per cent, and carbohydrate derived from cane, milk and grain sugars 30 per cent.

Calories.—320 per 100 Gm.

Use.—For conditions that require an increased intake of protein.

Maple Island Farm, Inc., Stillwater, Minn.

"VALLE VERDE LECHE EN POLVO" OR "MAPLE ISLAND'S POWDERED WHOLE MILK", a powdered whole milk with vitamin D₂ added in the form of irradiated ergosterol.

Analysis (submitted by manufacturer).—Butterfat 28.40 per cent, protein (N $\times$ 6.38) 26.35 per cent, lactose 37.47 per cent, ash 5.78 per cent, moisture 2.00 per cent and 400 U.S.P. units of vitamin D₂ per reconstituted quart.

Calories.—5.10 per gram; 145.00 per ounce.

Use.—Whole milk powder fortified with vitamin D₂ for general use where whole milk or whole milk solids are required.

BCG VACCINATION

Of the two methods of preventing tuberculosis, namely, segregation of infected persons and immunization of those exposed to infection, the latter, according to Birkhaug,¹ has not received sufficient emphasis in this country. The skeptical attitude toward immunization is reflected in the recent report of Levine and Sackett² on the results of BCG immunization in New York City. Those authors expressed the opinion that as a public health measure the routine vaccination of children from tuberculous homes is less advantageous than the removal of the tuberculous person from the home. While tuberculosis control programs, exclusive of vaccination, have reduced the death rate from tuberculosis in the United States from 200 to 36 per 100,000 population in the last forty years, Denmark, during the same period, utilizing both segregation and immunization, has reduced tuberculosis mortality from about 300 to 32 per 100,000 population. Holm³ stated that since 1940 vaccination with the bacillus Calmette-Guérin has been adopted in Denmark as an essential weapon in the fight against tuberculosis. All children with a negative tuberculin reaction in a tuberculous environment have been vaccinated, also the newborn, and on development of a positive reaction they have been permitted to remain in their environment. The Tuberculosis Dispensary of Copenhagen reported that morbidity and mortality of tuberculosis among the children in a tuberculous environment has been reduced following vaccination to almost zero. Holm expressed the belief that BCG vaccination gives considerable, although not absolute, protection. It protects almost completely against the morbid phenomena of the primary infection, and it also affords considerable protection against genuine tuberculosis of the various organs, in particular against pulmonary tuberculosis.

Even with the reduction in the incidence, 50,000 deaths from tuberculosis in the United States occurred in 1947, and the total number of tuberculous patients

in this country is about 500,000. According to Birkhaug only half of these persons are under treatment and only one fourth in hospitals and sanatoriums. Almost 180,000 frank cases of tuberculosis are left at large to infect the healthy population. In an attempt to improve a similar situation, Denmark, Norway and Sweden have entered on a nationwide BCG vaccination of the tuberculin-negative population under 50 years of age. In Norway, BCG vaccination was made compulsory in 1947 for all tuberculin-negative persons under 50 years of age.

The rapid decline in tuberculosis mortality has created a new factor of epidemiologic importance; namely, a great number of negative reactors, persons who failed to acquire specific resistance against tubercle bacilli by means of a mild childhood infection. Heimbeck⁴ of Norway made the important observation, since verified in other countries, that the victims of tuberculosis among student nurses working in tuberculosis wards were nearly always the tuberculin-negative reactors.

The BCG Advisory Committee of the state of New York⁵ reported that BCG vaccination is the only known practical method of reducing morbidity and mortality from tuberculosis. There is a general agreement that it is safe and that it serves to convert nonreactors to tuberculin to reactors through infection with avirulent and benign bovine tubercle bacilli. BCG vaccination has no value in treating tuberculosis.

Madsen of Norway made the important observation that the primary tuberculous complex produced in tuberculin-negative reactors by means of BCG vaccination is sufficient to protect against the progression of a subsequently superimposed virulent infection. The investigations of Heimbeck on student nurses, of Ferguson in Canada⁶ and of Rosenthal⁷ and his co-workers in Chicago confirmed that vaccination with BCG inhibits primary tuberculosis in a manner analogous with the specific resistance induced by spontaneous and clinically silent infection with virulent tubercle bacilli. The work of Aronson and Palmer⁸ among North American Indians is particularly significant because it was carried out on two groups of persons that are as comparable as humanly possible. In terms of cases per thousand person-years, the rates of mortality from tuberculosis were 24.3 and 4.7 respectively.

Birkhaug suggested that BCG vaccine should be recommended for extensive use in the United States in tuberculin-negative reactors in groups occupationally exposed to tuberculous infections and in population groups with high tuberculosis mortality and morbidity, and where there has been a known exposure to tuberculosis or where an exposure is likely to occur.

OLFACTORY DEPRESSANT

In 1934 Elsberg and Levy¹ suggested a simple method of measuring the acuteness of the sense of smell. The method consisted of injecting different volumes of odorous air into the nasal passages, the smallest volume which produced a sensation of the particular odor being taken as a measure of olfactory acuity. The Elsberg apparatus included bottles of fixed size, each containing a constant amount of odorous substance, such as coffee or citral. The bottles are closed by rubber stoppers, which contain inlet and outlet tubes. A nosepiece ending in two olives is connected with the outlet tube, which is closed with a pinchcock. The inlet tube is connected with a syringe by means of which measured volumes of air can be injected into the bottle. This volume is released into the nasal passages by pressing the pinchcock. The smallest volume of odorous air which produces a sensation of the particular odor three times in succession is recorded, the subject removing the nosepiece and resting for thirty to sixty seconds between tests.

Adopting this technic, Goetzel and Stone² of the Permanente Foundation, Oakland, Calif., demonstrated a diurnal cycle in olfactory acuity in human subjects. The pattern of these variations was found to be remarkably constant and intimately connected with the habitual dietary cycle. Meals, if taken at normal intervals, are regularly preceded by a period of increased olfactory acuity and followed by a period of decreased acuity. When food is ingested between meals the precibal increase fails to occur. When a meal is omitted, the postcibal decrease does not develop. The precibal increase in olfactory acuity is apparently a measure of increased appetite, while the postcibal decrease is apparently a measure of the resulting feeling of satiety.

As a practical application of this technic the California physiologists studied the effects on the sense of smell of oral administration of amphetamine sulfate. The ability of this drug to subdue the sensation of hunger is generally accepted. The drug is frequently used as an adjuvant in the treatment of obesity. The physiologic mechanism of this drug's action is still undetermined. Many physicians would attribute its anorexial action to an inhibition of gastric tone,³ while others would explain it as a result of an elevation of mood with the production of a sense of well-being.⁴ The theory that the resulting anorexia is due to a depressant effect on the olfactory sense, however, was

suggested by Ivy.⁵ This was deduced from his observation that the drug produces anorexia in dogs even after extrinsic denervation of the stomach and intestines.

Goetzel and Stone tested the Ivy theory by measuring the olfactory acuity of persons before and after oral administration of amphetamine sulfate. On the control days when no drug was given the olfactory acuity increased rapidly from 10 a. m. (beginning of experiment) to 12 o'clock. The acuteness then fell precipitately during the lunch period (12 to 1). By the end of this period the sense of smell was depressed below its initial (10 a. m.) level. From 1 p. m. on the acuity gradually increased, reaching about half the pre-lunch level by 5 p. m. (end of experiment).

On the test days 10 mg. of the drug was given orally at about 10:30 a. m. The normal increase in olfactory acuity did not occur and was replaced by gradual fall in acuity. The olfactory acuity remained subnormal till the end of the test (5 p. m.). There was an acceleration of the dulling effect on the sense of smell as a result of lunch. Similar depressing effects were produced when administration of the drug was delayed till immediately before lunch, and on days when the drug was administered in lieu of lunch. With a freely selected caloric intake at lunch time, there was without exception a 35 to 40 per cent voluntary reduction in caloric intake when the lunch was preceded by administration of the drug. In all subjects the drug produced a sensation of satiety.

From these and other observations Goetzel concludes that the functional state of the olfactory system is important in the regulation of the sensation complex of appetite and satiety and that the anorexia produced by amphetamine sulfate is due primarily to its depressant action on the olfactory sense.

PSYCHOANALYSIS

Unlike every other medical discipline, the tenets of psychoanalysis question the right or qualification of those who have not themselves been subjected to psychoanalysis to express any valid opinion on the subject.

Recently Hiram K. Johnson,¹ writing in the *Psychiatric Quarterly*, presented a critique of psychoanalysis from a sympathetic yet skeptical and scientifically detached attitude. "In looking over the literature," he says, "one often has the feeling that the Freudian analyst is less concerned with results than with the fact that he is solely in possession of the one system of psychodynamics which purports to be thoroughly scientific. . . . Rather grudgingly it is admitted by analysts that dream interpretation is a somewhat flexible matter and depends to a large extent

on the preoccupations, values and therapeutic aims which the analyst maintains."

Dr. Johnson points out the close similarity between the problems concerned in psychoanalysis and those dealt with in theology. All of the "neurosis-producing patterns" which Freudian analysis attempts to destroy have long been recognized as evil in the eyes of the theologian—long before a scientific terminology was considered. "It will be seen," Johnson states, "that the Freudian psychology regards the adult personality as a composite of Jekylls and Hydes, but is concerned exclusively with the Hydes. These, it sets about to deracinate by the infantile roots, using a bizarre yet historical and sometimes effective method of negative conditioning. The chief weapon, as has been noted, in this boggy hunting is a highly specialized variety of associations which are anything but 'free.'"

Johnson believes that the chief contribution of Freudian psychology to the science of human mind may turn out to be that it has stressed the historical development of personality and aided in bringing into focus memories, emotions and attitudes which generally belong to the fringes of consciousness. He says that the history of magic and experimental science reveals a tendency for each successive phase of culture to develop a blind spot for its cults and errors. "Freudian psychoanalysis illustrates this phenomenon [Johnson] and corresponds to the vogue of phrenology and animal magnetism in the preceding century."

Because today so many have a highly emotionally charged attitude toward psychoanalysis and the teaching of the school of Freud, it takes courage to publish such strong statements. If, however, psychoanalysis wishes to claim a place as a scientific subject comparable to that of physiology or pathology, its devotees must be prepared not only to receive such comments but to answer them in a detached and scientific manner which will satisfy the collective intelligence of the scientifically minded.

Current Comment

HYPERTENSION AND PHEOCHROMOCYTOMA

Tumors of chromaffin cells, pheochromocytoma or paraganglioma, are now recognized so frequently they no longer can be regarded as rare. They may occur in true pheochrome tissue anywhere, but they occur most frequently in the adrenal medulla. While usually single, they may be multiple, a fact of special importance in the surgical treatment of such conditions. MacKeith¹ has classed 91 per cent of pheochromocytomas in 165 cases as not cancerous; however, the nature and structure of this type of neoplasma merit more study. The production of epinephrine by the cells of pheochromocytoma is a perfect example of functional

activity by neoplastic endocrine cells. As reviewed and studied by Cahill,² pheochromocytoma may cause typical hypertension, paroxysmal and also continuous, oftener perhaps in children than in adults. Significant amounts of epinephrine have been demonstrated in the tumor tissue by assay as well as by special staining; abnormal amounts of epinephrine may occur in the blood of the patient. The handling of pheochromocytoma during operation may be dangerous because of release of epinephrine and should be postponed until all vessels surrounding the tumor or connected with it are ligated. If necessary in such circumstances, the immediate fall in pressure can be controlled by intravenous injection of epinephrine. On removal of all the tumor tissue there follows a permanent fall to normal of the blood pressure—a unique cure of hypertension by removal of its cause.

RHEUMATOID AGGLUTININATING GLOBULIN

A new serum reaction, a possible key to the biochemical puzzle of rheumatoid arthritis, is described by Rose¹ and associates of Columbia University. During complement fixation tests for rickettsialpox, the convalescent serum of a patient was observed to agglutinate unhemolyzed sheep erythrocytes. In addition to having suffered recently from rickettsial infection, the patient was also afflicted with rheumatoid arthritis in an active state. Further investigation revealed that the serum of this patient would agglutinate normal sheep erythrocytes only in dilutions less than 1:16. The same erythrocytes after being sensitized with a small amount of rabbit anti-sheep-antibody were agglutinated in a serum dilution as high as 1:2,048, a 128 fold differential titer. A study was then undertaken to determine in what circumstances a similar high differential was present in the serums of other patients. A study of 110 patients showed that a similar high differential occurs almost exclusively in the serums of patients with rheumatoid arthritis and that the agglutinin titer for sensitized sheep cells varies with the activity and severity of the arthritic process. In patients with other arthritic diseases and with clinically inactive rheumatoid arthritis, the differential agglutination titer falls to within normal limits. It is never more than sixteen times the titer of agglutinins for nonsensitized sheep erythrocytes. Differential sheep cell agglutination tests were carried out with the electrophoretically separated globulin in fractions of serums from patients with rheumatoid arthritis. The essential agglutinin occurs apparently quantitatively in the globulin fraction of such serum. The precise nature of this rheumatoid agglutinating globulin, however, has not been determined. These investigators believe that their simple sheep cell differential agglutinin test may be of value in determining the activity status of patients suffering from rheumatoid arthritis. It may also serve as an aid in the differential diagnosis between rheumatoid arthritis and other diseases with arthritic manifestations.

ORGANIZATION SECTION

Official Notes

PROPOSED SCIENTIFIC PROGRAM AT INTERIM SESSION

Nov. 30-Dec. 3, 1948

Auditorium, St. Louis

TUESDAY, NOVEMBER 30

P. M.

- 2:00 Lecture in Opera House on Hypertension. Irvine H. Page, Cleveland.
- 2:30 Lecture in Opera House on Problems of Delivery. Ralph Reis, Chicago.
- 3:00 Intermission.
- 3:30-5:00 Clinical Presentations on Obstetrics in Room S-1; Poliomyelitis in Room S-2; Arthritis in Room S-3; Cancer in Room S-6; Radiology in Room S-7; Laboratory in Room S-8, and Hypertension in Room S-10.

WEDNESDAY, DECEMBER 1

A. M.

- 9:00 Lecture in Opera House on Pediatrics. (Speaker to be announced.)
- 9:30 Lecture in Opera House on Position of the Laboratory in the Diagnosis and Control of Disease. F. W. Konzelmann, Atlantic City, N. J.
- 10:00 Intermission.
- 10:30-12:00 Clinical Presentations on Pediatrics in Room S-1; Poliomyelitis in Room S-2; *Diabetes in Room S-3; Dermatology in Room S-6; Radiology in Room S-7; Laboratory in Room S-8, and Hematuria in Room S-10.

P. M.

- 2:00 Lecture in Assembly Room 1 on Arthritis. (Speaker to be announced.)
- 2:30 Lecture in Assembly Room 1 on Common Skin Diseases. Everett Fox, Dallas, Texas.
- 3:00 Intermission.
- 3:30-5:00 Clinical Presentations on Obstetrics in Room S-1; Poliomyelitis in Room S-2; *Diabetes in Room S-3; Cancer in Room S-6; Radiology in Room S-7; Laboratory in Room S-8, and Heart in Room S-10.

THURSDAY, DECEMBER 2

A. M.

- 9:00 Lecture in Opera House on Hematuria. (Speaker to be announced.)
- 9:30 Lecture in Opera House on Jaundice. Sidney Portis, Chicago.
- 10:00 Intermission.
- 10:30-12:00 Clinical Presentations on Pediatrics in Room S-1; Poliomyelitis in Room S-2; *Diabetes in Room S-3; Dermatology in Room S-6; Jaundice in Room S-7; Laboratory in Room S-8, and Hematuria in Room S-10.
- 10:00 a. m. to 1:00 p. m.*

P. M.

- 2:00 Lecture in Opera House on Diagnosis and Early Treatment of Poliomyelitis. Thomas Gucker, Boston.
- 2:30 Lecture in Opera House on Heart. George R. Herrmann, Galveston, Texas.
- 3:00 Intermission.
- 3:30-5:00 Clinical Presentations on Obstetrics in Room S-1; Poliomyelitis in Room S-2; Diabetes in Room S-3; Cancer in Room S-6; Jaundice in Room S-7; Laboratory in Room S-8, and Heart in Room S-10.

FRIDAY, DECEMBER 3

A. M.

- 9:00 Lecture in Opera House on Cancer. C. P. Rhoads, New York.
- 9:30 Lecture in Opera House on Diabetes. E. P. Joslin, Boston.
- 10:00 Intermission.
- 10:30-12:00 Clinical Presentations on Pediatrics in Room S-1; Poliomyelitis in Room S-2; Arthritis in Room S-3; Dermatology in Room S-6; Jaundice in Room S-7; Laboratory in Room S-8, and Hematuria in Room S-10.

Washington Letter

(From a Special Correspondent)

Oct. 14, 1948.

Cost in Mental Hospitals Up 65 Per Cent

Statistics compiled by Mental Hygiene Division, U. S. Public Health Service, demonstrate the increasing cost of maintaining mental hospitals. Expenditures by such institutions, public and private, totaled approximately \$400,000,000 in 1947, an increase of \$154,000,000 over the figure for 1945, according to Public Health Service estimates. On a per capita basis, the increase was from \$470 per patient in 1945 to \$731 last year. It was pointed out by the Mental Hygiene Division that the steep rise is reflective not only of higher general price levels but also of improvement in quality of care given in mental hospitals during the early postwar years. Average daily resident patient population during 1947 was 540,000, compared with 525,000 in 1946 and 513,000 in 1945.

Illness and Off-Job Accidents Cause Most Absenteeism

Three fifths of the absenteeism among manufacturing workers results from illness and accidents away from work, according to findings of a joint study conducted by the Bureau of Labor Statistics, the Social Security Administration and the U. S. Public Health Service. The survey covered two hundred and forty-six plants in 1947. The average employee lost 9.6 working days during the year, of which illness and nonindustrial accidents accounted for 6.5 days, personal reasons 2.5 days and industrial injuries only 0.6 day. Seasonally, absenteeism rates were highest in the year's first quarter (when respiratory infections are at their height), declined substantially in the second, reached the lowest point in the third quarter and rose sharply in the fourth quarter.

Seven Military Medical Research Bases Inspected

The medical sciences committee of the Research and Development Board recently completed its first field trip, in the course of which it visited Army, Navy and Air Force research units at the following locations: Aero Medical Laboratory, Philadelphia; Special Devices Center, Sands Point, Long Island; Army-Navy Medical Procurement Office, Fort Totten, N. Y.; Climatic Laboratory, Lawrence, Mass.; U. S. Submarine Base, New London, Conn.; Army Nutritional Laboratory, Chicago; Aero Medical Laboratory, Wright-Patterson Air Force Base, Dayton, Ohio.

BCG Vaccinations in Alaska Progressing

The Bureau of Indian Affairs (Interior Department) has announced completion of its BCG vaccination program at Point Barrow, Alaska. Dr. Joseph D. Aronson, of Philadelphia, examined 600 Eskimos at the remote Alaskan outpost, and 250 of them received the antituberculosis vaccine. Similar work was done subsequently at Sitka and Wrangell, where 74 persons were vaccinated. Assisting Dr. Aronson were Drs. William Carr, contract physician in the service of the Navy Department; Elaine Schwinge, of the Territorial Department of Health; Ed Gloomquist, of Public Health Service, and Florence Marquis, detailed by the Public Health Service to the Territory of Alaska.

Advisory Committee to Children's Bureau Formed

The recently formed advisory committee to the Children's Bureau (Federal Security Agency) on federal-state programs for maternal and child health and services to crippled children held its first meeting in mid-September, and Dr. Harry H. Gordon, professor of pediatrics at University of Colorado Medical Center, was elected chairman. Serving with him are the following: Drs. Raymond B. Allen, Allan M. Butler, W. W. Bauer, Dean A. Clark, William J. Darby, M. Edward Davis, Kenneth A. Easlick, Nicholson J. Eastman, William T.

Green, Charles F. Good, Harry H. Gordon, John P. Hubbard, Herbert R. Kobes, William Mengert, James Raglan Miller, Oscar L. Miller, Harry A. Ong, John Z. Preston, Abraham Barhash, Duncan E. Reid, Hugh B. Robins, Nathan Sinai, Thomas E. Shaffer, Ernest Stebbins, Felix J. Underwood, Abram L. Van Horn, R. M. Walls and James L. Wilson; also, George Bugbee, executive director, American Hospital Association; Harriett M. Bartlett, Simmons College; Hazel Corbin, R.N., New York Maternity Center Association; Claudia Durham, R.N., Meharry Medical College; Mrs. Lulu Evanson, National Farmers Union; Katharine Faville, R.N., dean, Wayne University College of Nursing; Lawrence J. Linck, executive director, National Society for Crippled Children and Adults; Mary Blanche Moss, executive secretary, American Association of Medical Social Workers; Ewell Newman, National Urban League; Harry Read, Congress of Industrial Organizations; Raymond Rich, New York City; Edward S. Rogers, University of California School of Public Health; Catherine E. Sheckler, R.N., American Nurses' Association; Randel Shake, American Legion; Florence C. Thorne, American Federation of Labor; Mrs. Roy C. F. Weagley, American Farm Bureau Federation; Barbara White, American Physiotherapy Association; Mrs. Eva Ylvisaker, American Dietetic Association; Mrs. C. D. Lowe, National Congress of Parents and Teachers; Mrs. Stella Scurluck, General Federation of Women's Clubs, and Mrs. Edith Hyslop Sherrard, American Association of University Women.

Meetings of the committee will be twice yearly, or oftener, at the call of the Children's Bureau.

Organize Advisory Body on Streptococcus Infections

Newest branch of the Army Epidemiological Board to be formed is the Commission on Streptococcal Infections, which held its organization meeting in Washington September 20. The chairman is Dr. W. S. Tillett, of New York City. From three to five members and about six associate members will comprise the commission, whose composition is not yet completed. The September 20 meeting was devoted largely to discussion of major problems which will confront the unit, including the need of stimulating research in order to gather more information on World War II incidence in the armed forces, basic immune processes and the various types of streptococci. Also discussed were plans for studies on prophylaxis, utilizing penicillin and sulfonamide compounds, which the Army will conduct this winter at certain camps in the Rocky Mountain area of the country.

The Army Epidemiological Board's Commission on Virus and Rickettsial Diseases, of which Dr. John R. Paul is director, will meet on September 30 to discuss the recent outbreak of Japanese B encephalitis in Japan, which to date has claimed an estimated 6,000 cases.

Commission Announces Fellowship Awards

Award of one hundred and sixty-two research fellowships in the biologic, physical and agricultural sciences has been announced by the Atomic Energy Commission. The successful applicants, representing thirty states, will study in forty-three research and educational institutions. Three of the five postdoctoral biologic fellowships awarded will be taken at the University of California and one each at New England Deaconess Hospital (Boston) and Harvard University. All but nineteen of the awards are predoctoral fellowships, whose fields of study will include biologic action of radiation, tracer studies, pathologic effects of radioactive iodine, mechanism of vitamin D activity, hormone investigations and health physics.

Supplies Marked for October Sales

Hospital and laboratory equipment, drugs and miscellaneous supplies are included among federal war surplus property which will be placed on sale by the War Assets Administration in October. Information on the sales, which will be conducted in various parts of the country, may be obtained from the War Assets Administration offices in Chicago, Detroit, Cincinnati, St. Louis, Philadelphia, and Trenton and Linden, N. J.

Booklet Describes Dangers of Abandoned Mines

A booklet, "Hazards of Entering Old Workings," recently issued by Bureau of Mines (Department of Interior) describes the perils to health and limb that lurk in abandoned mines, quarries and open pits. Anoxia and gas poisoning, illness caused by drinking polluted water, snakebites and spider stings, cave-ins—these are among the hazards cited. "Hazards of Entering Old Workings," also known as Information Circular 7479, may be obtained without cost from the Bureau of Mines, Publications Distribution Section, 4800 Forbes Street, Pittsburgh 13, Pa.

Coming Medical Meetings

American Medical Association Interim Session, St. Louis, Municipal Auditorium, Nov. 30-Dec. 3. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

Annual Conference of State Secretaries and Editors, St. Louis, Hotel Statler, Nov. 28-29. Dr. George F. Lull, 535 N. Dearborn St., Chicago 10, Secretary.

National Medical Public Relations Conference, St. Louis, Hotel Statler, Nov. 27. Mr. Lawrence W. Rember, 535 N. Dearborn St., Chicago 10, Director.

American Academy of Dermatology and Syphilology, Chicago, Palmer House, Dec. 5-9. Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, Secretary.

American Academy of Ophthalmology and Otolaryngology, Chicago, Palmer House, Oct. 10-15. Dr. W. L. Benedict, 100 First Avenue Bldg., Rochester, Minn., Secretary.

American Academy of Pediatrics, Atlantic City, Chalfonte-Haddon Hall, Nov. 20-23. Dr. Clifford G. Grulee, 636 Church St., Evanston, Ill., Secretary.

American Association of Railway Surgeons, Chicago, Nov. 21-23. Dr. Raymond B. Kepner, 547 W. Jackson Blvd., Chicago 6, Secretary.

American Clinical and Climatological Association, Hot Springs, Va., The Homestead, Nov. 8-10. Dr. James Bordley III, Bassett Hospital, Cooperstown, N. Y., Secretary.

American College of Surgeons, Los Angeles, Biltmore Hotel, Oct. 18-22. Dr. Paul B. Magnuson, 40 E. Erie St., Chicago 11, Secretary.

American Public Health Association, Boston, Nov. 8-12. Dr. Reginald M. Atwater, 1790 Broadway, New York 19, Executive Secretary.

American Society for the Study of Arteriosclerosis, Chicago, Hotel Knickerbocker, Oct. 31-Nov. 1. Dr. O. J. Pollak, Quincy City Hospital, Quincy 69, Mass., Secretary.

American Society of Anesthesiologists, St. Louis, Hotel Statler, Nov. 4-6. Mr. John H. Hunt, 188 W. Randolph St., Chicago 1, Executive Secretary.

American Society of Clinical Pathologists, Chicago, Oct. 10-16. Dr. A. S. Giordano, 531 N. Main St., South Bend 1, Ind., Secretary.

Association for Research in Nervous and Mental Diseases, New York, Waldorf-Astoria Hotel, Dec. 10-11. Dr. Clarence C. Hare, 700 W. 168th St., New York 32, Secretary.

Association of Military Surgeons of the United States, San Antonio, Texas, Nov. 11-13. Dr. James M. Phalen, Army Institute of Pathology, Washington 25, D. C., Secretary.

Indiana State Medical Association, Indianapolis, Oct. 26-28. Mr. Ray E. Smith, 23 E. Ohio St., Indianapolis 4, Executive Secretary.

International College of Surgeons, U. S. Chapter, St. Louis, Kiel Auditorium, Nov. 16-19. Mr. Ralph E. Osborne, 1516 Lake Shore Drive, Chicago, Business Secretary.

Inter-State Postgraduate Medical Association of North America, International Medical Assembly, Cleveland, Public Auditorium, Nov. 9-12. Dr. Tom B. Throckmorton, 406 Sixth Ave., Des Moines, Iowa, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Biltmore Hotel, Oct. 25-28. Mrs. M. R. Waller, 512 Medical Arts Bldg., Oklahoma City, Executive Secretary.

Omaha Mid-West Clinical Society, Omaha, Hotel Paxton, Oct. 25-29. Dr. John M. Thomas, 1031 Medical Arts Bldg., Omaha 2, Secretary.

Puerto Rico, Medical Association of, Santurce, Dec. 10-12. Dr. J. Basora Delfillo, Box 3866, Santurce, Secretary.

Radiological Society of North America, San Francisco, Dec. 5-10. Dr. Donald S. Childs, 607 Medical Arts Bldg., Syracuse 2, New York, Secretary.

Southern Surgical Association, White Sulphur Springs, W. Va., Dec. 7-9. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Southwestern Medical Association, El Paso, Texas, Oct. 28-30. Dr. Wickliffe R. Curtis, First National Bank Bldg., El Paso, Secretary.

Western Surgical Association, St. Louis, Dec. 2-4. Dr. Warren H. Cole, 1853 W. Polk St., Chicago 12, Secretary.

Virginia, Medical Society of, Richmond, John Marshall Hotel, Oct. 18-20. Miss Agnes V. Edwards, 1200 E. Clay St., Richmond 19, Secretary.

GOVERNMENT SERVICES

PUBLIC HEALTH SERVICE

COST OF LONG TERM MENTAL CARE

During 1947 the cost of providing long term hospital care in mental hospitals was approximately \$400,000,000, according to estimates of the Mental Hygiene Division of the Public Health Service. Between 1945 and 1947, expenditures for maintenance in hospitals providing long term care for psychiatric patients increased by \$146,000,000, or approximately 60 per cent of the estimated expenditures for 1945. In terms of the annual cost per patient, or per capita expenditure, the increase was about 50 per cent, from \$480 in 1945 to \$727 in 1947. This increase reflects in large part the increase in the general price level during the period but may also reflect to some degree improvement in the quality of mental hospital care during the postwar period.

The estimates presented here are based on figures from a variety of sources. For state, psychopathic and Veterans Administration neuropsychiatric hospitals these figures are reasonably complete; for county and city hospitals and private hospitals, however, the basic data are somewhat fragmentary; the estimates are in some instances based on the assumption of a constant relationship between annual changes for these two types of hospitals, respectively, and corresponding changes for state hospitals. In view of this situation, estimates of expenditures have been rounded to the nearest million, and those of average daily population to the nearest thousand. Figures on per capita expenditures are based on the initial unrounded absolute numbers.

ADVANCED TRAINING FOR MEDICAL OFFICERS

Six officers of the U. S. Public Health Service have been awarded Rockefeller fellowships for graduate study in public health. They are Surgeons Elton Osborne Jr. and Mary Walton, and Assistant Surgeon Clarence A. Velat, at Johns Hopkins University; Senior Surgeon (R) S. J. Axelrod, at the University of Michigan; Senior Assistant Surgeon George Adams, at Yale, and Senior Assistant Surgeon George A. Spendlove, at Harvard.

Other Public Health Service officers receiving advanced training are Surgeons Samuel C. Ingraham, who is beginning a year's training in radiobiology at the University of Colorado Medical School, Denver; John B. Vander, at the Massachusetts Institute of Technology for part time training in radiobiology; and Senior Surgeon Kirkland C. Brace, at University of Chicago for advanced training in radiobiology. Surgeon Mary A. Diamond is assigned to the Columbia University College of Physicians and Surgeons, New York, for study in neurology and psychiatry; Senior Surgeon Vernam T. Davis is in psychiatric training at William A. White Institute of Psychiatry, New York; Senior Assistant Surgeon Robert B. Dorsen will

attend the University of Pennsylvania for a year's study in obstetrics and gynecology; Senior Assistant Surgeon Rheim M. Jones will attend the New York Postgraduate Medical School for a course in surgery of the eye, and Senior Assistant Robert C. Rodger will study pathology and diagnostic bacteriology at Johns Hopkins University.

FEDERAL GRANTS FOR UNDERGRADUATE COURSES

The U. S. Public Health Service announces that federal grants for undergraduate courses are now being offered to medical schools to foster training of students in the mental aspects of disease. Formerly, grants to medical schools authorized by the National Mental Health Act were used primarily for graduate training in psychiatry. The extension of these grants to the undergraduate field was recommended by the National Advisory Mental Health Council as a means of providing future physicians with the basic knowledge that will help them recognize early symptoms of mental illness, treat cases which do not require the service of a specialist and apply psychiatric treatment to various types of illness.

Applications should be made to the Mental Hygiene Division of the Public Health Service, Washington, D. C., by Oct. 15, 1948. Some selection of schools will be necessary, because of limited funds, although eventually it is expected that all medical schools that desire such assistance may receive grants. The amounts to be allocated to each school selected will be based on the recommendation by the National Mental Health Council, but with the funds now available it will not be possible to grant more than \$37,500 to a school for the first three year period.

DIAGNOSTIC CANCER TESTS

The National Cancer Institute and a group of medical schools and hospitals will cooperate in a program to determine which of the many reported diagnostic tests are dependable, and in refining the most promising tests and in developing new tests. The Director of the National Cancer Institute, Dr. J. R. Heller, states that negotiations leading up to this program have been in progress the past year and have resulted in a tentative program which includes clinical and laboratory studies carried out simultaneously in the cooperating medical schools and hospitals with the necessary coordination and direction centering in the National Cancer Institute. Tests that show promise in the laboratories will first be applied to a small number of thoroughly studied cases and then, if justified, to thousands of persons with and without cancer, particularly to those passing through the United States Public Health Service Medical Center at Hot Springs, Ark., where National Cancer Institute already operates a pilot cancer detection unit.

MISCELLANEOUS

THE GOVERNMENT NEEDS PHYSICIANS

The United States Civil Service Commission announces an examination for filling medical officer positions open in some twenty-eight medical fields ranging from general practice through the various specialties. The positions are located in Washington, D. C., throughout the United States and in the Panama Canal Zone, in such agencies as the Indian Service, Panama Canal Service, United States Public Health Service, Department of the Army, Veterans Administration, Civil Aeronautics Administration, and the Railroad Retirement Board. The salaries range from \$4,479 to \$6,235 a year.

No written test will be required. To qualify, applicants must be graduates of a medical school and must be currently licensed to practice medicine and surgery. For positions paying \$4,479

and \$5,232, applicants must have completed a full internship, either general rotating or in a specialty (this requirement is waived for some positions); and for positions paying \$5,232 and \$6,235, they must have had professional medical experience. Maximum age limits are as follows: for Panama Canal Service, 45 years; for Indian Service, 50 years; for other agencies, 62 years. For persons entitled to veteran preference, the 45 and 50 year age limits are waived to 62 years, and the 62 year age limit is waived without limitation.

Information and application forms may be secured at most first and second class post offices, from Civil Service regional offices, or from the United States Civil Service Commission, Washington 25, D. C. Applications will be accepted in the Commission's Washington office until further notice.

Medical News

(Physicians will confer a favor by sending for this department items of news of general interest: such as relate to society activities, new hospitals, education and public health. Programs should be received at least two weeks before the date of meeting.)

CALIFORNIA

Nutrition Study of Aged.—A nutrition study of older people is being conducted in San Mateo County through the cooperation of the local health department, the College of Agriculture for the University of California at Berkeley, the U. S. Department of Agriculture, the U. S. Public Health Service and the California Department of Public Health. Federal agencies are supplying a team of experts who will be guided by an advisory committee representing various California health and agricultural agencies. The study will attempt to determine the nutritional status of a selected group of institutionalized and noninstitutionalized aged persons.

COLORADO

Professor Schmidt Goes to New Orleans.—Dr. Ernest A. Schmidt has resigned as professor and head of the department of radiology of the University of Colorado Medical Center to take up new duties at Touro Infirmary, New Orleans. The department of radiology will be under the administration of a departmental committee until a new professor and head of the department can be appointed.

Research on Epilepsy.—The University of Colorado Medical School, Denver, has received a grant of \$5,000 from the Easter Seal fund of the Colorado Division of the National Society for Crippled Children and Adults for treatment and research in the field of epilepsy. The university's program will be headed by Dr. Harriot H. Hunter of the Epilepsy Clinic. The grant provides for a director, honorariums for two medical assistants and a social worker and for administrative services and supplies. The program calls for a registry of epileptics and a work shop to provide group therapy for parents as well as patients.

DISTRICT OF COLUMBIA

Appoint Professor of Urology.—Dr. Lloyd G. Lewis, associate professor of urology, has been appointed professor of urology at the Georgetown University Medical Center. A graduate of Johns Hopkins University School of Medicine, Baltimore, 1928, Dr. Lewis served as an instructor, associate, and assistant professor of urology there and assistant visiting urologist at Johns Hopkins University Hospital, 1933-1942. He served in the army during World War II as chief of the urologic section of the Walter Reed General Hospital. He is now a consultant in genitourinary surgery to the Secretary of War and Walter Reed General Hospital.

DELAWARE

Dedicate the Governor Bacon Health Center.—This center, which is a part of the Delaware State Hospital at Farnhurst, was dedicated September 27. It will accommodate 282 children in various psychotic states, epileptics without psychoses, crippled children or children waiting for assignment to foster homes, and 266 adults, who are epileptic, alcoholic or senile and bedridden. The center will provide modern diagnostic and therapeutic facilities. Its objective is complete or partial rehabilitation of children on the statewide basis for all classes of people. It will also be an educational and training center and will closely affiliate with the New York and Pennsylvania universities, the Alfred I. DuPont Institute, Delaware State Hospital and all general hospitals and the health and welfare agencies of the state.

ILLINOIS

Two Day Institutes on Venereal Disease.—The Illinois Department of Health, through its divisions of venereal disease control and public health nursing, is sponsoring three two-day institutes on venereal disease control. The first is scheduled for November 15-16 at the Kaskaskia Hotel in LaSalle, the second on November 17-19 at the St. Nicholas Hotel in Springfield and the third on November 23-24 at the Hotel Emerson in Mt. Vernon. Some of the subjects to be discussed are: Facilities for the Treatment of Venereal Diseases, Health Education and Venereal Diseases Control, and Drugs Used in the Treatment of Gonorrhea.

Evanston Hospital Expands.—Three additions are planned for the Evanston Hospital. Ground-breaking ceremonies October 1 marked the beginning of a six story addition to the west end of the main building and a two story connection with the Abbott Memorial Laboratory. The new building will add ninety-two beds. The second building in the expansion program will be a maternity building, and the third will provide facilities for psychiatric care and tuberculous patients, a pediatrics division, a dental clinic and a tumor clinic in connection with the outpatient department.

Chicago

Dr. Harvey to Address Institute of Medicine.—Dr. A. McGee Harvey, professor of medicine, Johns Hopkins University School of Medicine, Baltimore, will deliver the annual lecture before the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine October 22 at the Palmer House on "Some Physiological Experiments of Nature in the Field of Neuromuscular Function. Potassium Deficiency, Potassium Intoxication, Myasthenia Gravis."

Prize for Paper on Surgery.—The Chicago Surgical Society awards an annual prize for a manuscript describing experimental work in one or both fields of experimental and clinical surgery. Applicants must be residents of Cook County. All identification marks of the author and of the hospital or institution in which the work was performed must be eliminated from the manuscript. The paper should be submitted to the Secretary, Dr. C. B. Pruestow, Room 910, 30 N. Michigan Avenue, not later than March 1, 1949, accompanied by a sealed envelope bearing on its outside the title of the paper and containing within it the name and address of the author.

Medal Awarded to a Dog.—The National Society for Medical Research on October 1 presented a medal to an experimental animal, a dog, for its part in the advancement of research on cardiovascular surgery. The presentation was made by Dr. Andrew C. Ivy, vice president of the University of Illinois, on a televised program over station WBKB. Seventy-six children in the Chicago area owe their lives to this dog, Caesar, which played a part in the original research at Children's Memorial Hospital. Two former "blue babies" also appeared on the program. The presentation was part of a health education program of the American Medical Association developed in cooperation with the educational committee of the Illinois State Medical Society and the National Society for Medical Research.

Eight Professors Appointed.—Appointment of eight physicians to positions of professorial rank on the faculty of the University of Illinois College of Medicine have been announced: Dr. S. Howard Armstrong Jr., has been appointed professor of medicine. A graduate of Princeton University, Princeton, N. J., and Harvard Medical School, Boston, 1937, Dr. Armstrong now serves as chairman of the department of medicine at Presbyterian Hospital. Drs. William S. Hoffman and Robert Eugene Johnson have been named professorial lecturers in physiology. Dr. Hoffman serves as director of biochemistry at Cook County Hospital Laboratories and Hektoen Institute for Medical Research. Dr. Johnson holds the position of director of research at the Army Medical Nutrition Laboratory. Drs. Samuel A. Leader and Harry Slobodin have been appointed to the faculty with the rank of clinical assistant professor of radiology. Dr. Leader, a graduate of the University of Chicago and Rush Medical College, is chief of diagnostic x-ray at Vaughn Unit, Veterans Administration Facility, Hines. Dr. Slobodin, a graduate of Columbia University and New York University College of Medicine, New York, has served as chief of the department of radiology at the Veterans Hospital since 1942. Dr. Rudolph G. Novick, director of the Illinois Society for Mental Hygiene, has been appointed clinical assistant professor of psychiatry. Joseph E. Bourque, Ph.D., has been appointed an assistant professor of physiology. He previously taught at Wayne University College of Medicine, Detroit. Dr. James A. Campbell has received an appointment as assistant professor of medicine. A graduate of Knox College, Galesburg, Ill., and Harvard Medical School, Boston, he now serves as assistant attending physician at Presbyterian Hospital.

IOWA

Otolaryngology Conference.—The State University of Iowa College of Medicine, Iowa City, is sponsoring a conference in otolaryngology November 29-December 3. Guest speakers will be Drs. Kenneth M. Day, Pittsburgh; French K. Hansel, St. Louis; Frederick T. Hill, Waterville, Maine; Paul H. Holinger, Chicago; Gordon D. Hoople, Syracuse, N. Y.; Julius Lempert, New York, and James H. Maxwell, Ann Arbor, Mich. Enrollment is limited to 25, and the registration fee is \$75. Inquiries and applications should be addressed to Dr. J. T. McClintock, Director of Postgraduate Studies, Room 259, Medical Laboratory Bldg., Iowa City.

Public Health Appointment.—Dr. Ralph H. Heeren, formerly of the Oklahoma City Health Department, has taken over duties as director of Preventable Diseases and Venereal Disease for the Iowa State Health Department. He succeeds Dr. Carl F. Jordan, resigned. Dr. Heeren obtained his medical degree from the State University of Iowa College of Medicine, Iowa City, 1934, and did graduate work at Western Reserve University, Cleveland, and at Harvard School of Public Health, Boston. He has taught medical bacteriology at the State University of Iowa, Western Reserve and Tulane University of Louisiana School of Medicine, New Orleans. He has had experience in state health work in Iowa, Louisiana and Oklahoma.

MICHIGAN

Record Attendance.—Registration records were broken at the annual meeting of the Michigan State Medical Society in Detroit, September 22-24. A total of 3,382 attended the three day postgraduate conference, 2,734 of which were doctors of medicine.

Dr. Stevenson Appointed Professor of Obstetrics.—Dr. Charles S. Stevenson, formerly of Boston, has been appointed professor of obstetrics and gynecology and head of the department at Wayne University College of Medicine, Detroit. Dr. Stevenson received his medical degree at Johns Hopkins School of Medicine, Baltimore, and was resident gynecologist at the hospital and resident obstetrician at the Boston Lying-In Hospital.

Sight-Saving Program.—The Michigan State Department of Health reports that poor eyesight handicaps 1 out of every 5 Michigan school children. Last year the department undertook a vision conservation program to help local agencies and groups in the prevention and correction of sight defects of children and improving the visual environment in school and in homes. The department's vision consultant was invited into 27 counties and to teacher's colleges, institutes and workshops. Nine counties carried on a program in which the sight of all school children was tested. Of 33,585 children tested, 3,864 showed some sight defects. In addition, there were 2,748 children who were under treatment or who had undergone treatment for eye conditions. Equipment, material and the services of the vision consultant are available on request through the local health department or, where there is no such department, directly through the Michigan Department of Health, Lansing 4, Mich.

MINNESOTA

Lecture on Gastric Secretion.—The second annual Phi Delta Epsilon medical lectureship will be given at the University of Minnesota, medical sciences amphitheater, November 3, 8 p. m., by Franklin Hollander, Ph.D., head of the Gastroenterology Research Laboratory of the Mount Sinai Hospital, New York, on "Studies in Gastric Secretion." The lecture is presented under the combined auspices of the University of Minnesota Medical School, the Phi Delta Epsilon undergraduate fraternity and the Minnesota Phi Delta Epsilon graduate club.

NEW YORK

Open New Psychiatric Wing.—Strong Memorial Hospital's new \$1,000,000 psychiatric wing at Rochester was opened for study and treatment of the emotionally ill August 27. Present services for a time will be restricted to outpatient visits daily.

Postgraduate Courses.—The Medical Society of the State of New York, in cooperation with the New York State Health Department, has arranged a postgraduate lecture at the University Club, Syracuse, October 19, at 8:30 p. m. Dr. Isadore Snapper, New York, will speak on "Osseous Manifestations of Medical Diseases." A series of postgraduate lectures have been arranged for the Schoharie County Medical Society on Tuesday afternoon at 4 o'clock at the Cobleskill High School Building, Cobleskill.

Oct. 19—Chester E. Clark, Syracuse, Gynecology in General Practice.
Nov. 2—Richard S. Farr, Syracuse, Disabilities of the Foot and Ankle.
Nov. 16—Ethel G. Cermak, Albany, Rheumatic Fever.
Nov. 30—Alfred Weintraub, New York, The Ophthalmoscope in the Diagnosis of General Diseases.

On November 17 the Sullivan County Medical Society will hear Dr. Paul A. Bunn, Syracuse, speak on "Recent Advances in Therapy" at the Monticello Hospital, Monticello, 8:30 p. m.

The Onondaga County Medical Society will hear Dr. Alexander Brunschwig, New York, speak on "Radical Surgery for Cancer" at a meeting at the University Club, Syracuse, November 9, 8:30 p. m.

Advisory Council to Aid in State Mental Health Program.—An advisory council, representing various aspects of community activity in the fields of psychiatry, social welfare, general medicine and public health, has been appointed to advise

the Department of Mental Hygiene in the expansion of New York State's mental health program. It will meet monthly with the commissioner of mental hygiene, Dr. Frederick MacCurdy. Dr. Howard W. Potter, professor of psychiatry at the Long Island College of Medicine, is chairman of the council. Other members are: Dr. Edward A. Sharp, New York; Dr. S. Bernard Wortis, New York, representing the Medical Society of the State of New York; Dr. J. Lawrence Pool, New York; Dr. L. Whittington Gorham, Albany; Marian F. McBee, executive secretary of the New York Committee on Mental Hygiene; Ralph King, president of the New York State County Welfare Association, and Henry J. A. Collins, judge of the Children's Court in Nassau County. Among the projects on which the council will aid the commissioner and his staff is a more comprehensive educational program to promote mental health of children. The council will also assist the department in securing cooperation with hospitals and developing plans for improving care of mentally ill patients in general hospitals.

New York City

Personal.—Dr. I. Paul Train was recently promoted to assistant professor of surgery at New York Medical College and assistant attending surgeon at Flower-Fifth Avenue Hospital. He is a graduate of New York Medical College, Flower and Fifth Avenue Hospitals, 1930.

First Harvey Lecture.—Dr. Cecil J. Watson, professor of medicine, University of Minnesota Medical School, will deliver the first Harvey Lecture on "Urobilin and Stercobilin" before the members of the Harvey Society in affiliation with the New York Academy of Medicine October 26, at 8:30 p. m.

Wilson Memorial Lecture.—Dr. Anton J. Carlson, professor emeritus of physiology, University of Chicago, will lecture on "Diet and the Span of Life," October 19 at 4:15 p. m., in the North Lounge of Hunter College. This is the second in the annual Margaret Barclay Wilson Memorial Lecture series, established by the department of physiology, health and hygiene, Hunter College, as a tribute to the memory of its first chairman.

Symposium on Rehabilitation.—The Association of Military Surgeons of the United States, Metropolitan New York Chapter, will hold a Symposium on Rehabilitation at the New York University Bellevue Institute of Rehabilitation and Physical Medicine, October 27 at 8:30 p. m. The speakers will be:

Howard A. Rusk, The Place of Rehabilitation in the Practice of Medicine.

Donald A. Covalt, Rehabilitation—Its Place in the General Hospital.

Morris Grayson, Emotional Factors in Physical Disability.

George G. Deaver, Rehabilitation of Motor Disabilities.

Sixteenth Series of Salmon Lectures.—Torbjørn O. Caspersson of the Nobel Institute, Stockholm, will give the sixteenth series of the Thomas William Salmon Lectures at the New York Academy of Medicine on the evenings of November 8-10, under the general title of "Cell Function and Cell Growth in Normal and Pathologic Conditions, Studied by Quantitative Cytochemical Procedures." Dr. Caspersson, biophysicist and biochemist, is professor of medical cell research and genetics and director of the Institute for Cell Research of the Medical Nobel Institute in Stockholm.

OHIO

Tuberculosis Clinics.—The Westside County Tuberculosis Clinic opened September 21 as an outpatient department of Sunny Acres Sanatorium, Cleveland, in cooperation with the Sixth Health District. Open daily, it will operate as a diagnostic and case-finding clinic. Another clinic is now under construction on the east side of the city and will be finished within a year. These new clinics together with the new Cleveland Health Center to be opened by the end of 1948, the other health centers now operating and the three county mobile x-ray units will provide Cleveland with excellent facilities for tuberculosis case finding.

Course in Chest Diseases.—The Ohio State Medical Association is offering a postgraduate course in Diagnosis and Treatment of Chest Diseases at the Elks Home, Chillicothe, October 21, beginning at 2 p. m. Physicians from all sections of the state are invited. Speakers will be:

John H. Skavlem, Cincinnati, Pathogenesis and Clinical Considerations.
William L. Potts, Columbus, Laboratory Aids in Diagnosis of Pulmonary Diseases.

David W. Heusinkveld, Cincinnati, Chest Films.

Joseph B. Stocklen, Cleveland, Planning the Management of the Tuberculous Patient.

Maurice G. Buckles, Columbus, Developments in Chest Surgery.

Sidney E. Wolpaw, Cleveland, Drug Therapy.

Arnold B. Kurlander, Columbus, Community Tuberculosis Control Measures.

John H. Skavlem, Cincinnati, Panel Discussion.

OREGON

State Medical Election.—At the meeting of the Oregon Medical Society, September 15-18, Dr. Leslie S. Kent, Eugene, was installed as president and Dr. James E. Buckley, Portland, was named president-elect; Dr. Werner E. Zeller, Portland, secretary, and Dr. Allen O. Pitman, Hillsboro, treasurer.

Appointed to Board of Health.—The Oregon State Board of Health has appointed Dr. George C. Gibson, Ravenna, Ohio, as director of the cancer section of the state department of health. Dr. Gibson received his medical degree from Harvard Medical School, Boston, in 1943, served with the U. S. Public Health Service Marine Hospital, Brighton, Mass., and for two years at the Ponderville Hospital at Walpole.

PENNSYLVANIA

To Direct State Bureau of Laboratories.—Arthur P. Hitchens, Lieutenant Colonel (M.C.), U. S. A., retired, formerly professor of public health and preventive medicine at the University of Pennsylvania School of Medicine, Philadelphia, has been appointed to succeed Dr. Claude P. Brown as director of the Bureau of Laboratories of the Pennsylvania State Department of Health. Dr. Brown has been connected with the bureau for seven years and will devote his entire time to clinical pathology.

Philadelphia

University Appointment.—Phyllis A. Bott, Ph.D., has been made professor of physiologic chemistry and chairman of the department at the Woman's Medical College of Pennsylvania. Dr. Bott, a graduate of the University of Wisconsin, Madison, became associate professor at Woman's Medical College in 1941 and in 1946 succeeded Marion Fay, Ph.D., professor of physiologic chemistry, as chairman of the department when Dr. Fay was made dean.

Strittmatter Award.—The Philadelphia County Medical Society has presented its Dr. I. P. Strittmatter Award for 1947 to Dr. Pascal F. Lucchesi "in recognition of his outstanding service to medical education and to the public health in Philadelphia" lately as medical director and superintendent of the Philadelphia General Hospital and formerly as medical director and superintendent of the Philadelphia Hospital for Contagious Diseases. The award, a gold medal and scroll, was made possible through the generosity of Dr. Strittmatter to foster high ideals and distinguished service to the credit of the medical profession in the interest of humanity.

TENNESSEE

Personal.—Dr. John L. McGehee, professor and chief of the division of surgery at the University of Tennessee College of Medicine, Memphis, and surgeon-in-chief at John Gaston Hospital, retired September 1, but will retain his private practice. He has been associated with the university for forty-six years.

Dr. Blassingame Appointed Department Head.—Dr. Charles D. Blassingame, associate professor of otolaryngology since 1934, has been appointed professor and head of the department of otolaryngology at the University of Tennessee College of Medicine, Memphis, succeeding Dr. W. Likely Simpson, who has resigned to devote more time to private practice. Dr. Blassingame is a graduate of Vanderbilt University School of Medicine, Nashville, 1916, and is on the staff of Baptist Memorial Hospital.

TEXAS

Spanish-Speaking Physicians.—Jacob M. Gershberg of New York, president of the International Spanish Speaking Association of Physicians, Inc., was the chief speaker at a banquet in his honor given by the El Paso chapter, September 17. Dr. Gershberg has recently formed new chapters in Juarez, Mexico; Beverly Hills, Calif.; Reno, Nev., and Hot Springs, Ariz., bringing the number of chapters to fifty-nine.

New Postgraduate School at Houston.—The University of Texas' postgraduate school of medicine was established in Houston, September 18, and Dr. Randolph L. Clark Jr., director of the M. D. Anderson Hospital for Cancer Research, Houston, was appointed dean and professor of surgery. The school will ultimately be located in a separate building in the Texas Medical Center. Dr. Clark, a graduate of the Medical College of Virginia, Richmond, in 1932, has been director of the hospital since early in 1947. From 1938-1940 he was on the staff of Mayo Clinic, Rochester, Minn. He was consulting surgeon for the Mississippi State Charity Hospital, Jackson, and Mississippi State Tuberculosis Sanitarium. During the late war, he was chief of the surgical service of the Army Fair-Forces Technical Training School.

WEST VIRGINIA

Heart Association Meeting.—The fall meeting of the West Virginia Heart Association will be held at Morgantown October 29. A scientific program will be presented in the afternoon and evening, and a dinner is being arranged in connection with the meeting. Dr. T. Duckett Jones, Boston, will be the principal speaker. Requests for hotel and dinner reservations should be addressed to the secretary, Dr. Fred Richmond, Beckley.

Public Health Appointment.—The division of maternal and child health of the state health department announces the acceptance by Dr. Walter W. Point, Charleston, of appointment as part time obstetrical consultant. He will assist the division in planning the state maternal and child health program. Dr. Point has also been appointed by the public health council as a member of the advisory committee to the division of cancer control of the state health department. He will fill the vacancy caused by the death of Dr. J. Ross Hunter, Charleston.

GENERAL

Postgraduate Medical Assembly.—The International Medical Assembly of the Inter-State Postgraduate Medical Association of North America will meet in the Public Auditorium, Cleveland, November 9-12, under the presidency of Dr. Herman L. Kretschmer, Chicago. A program of diagnostic clinics, addresses and exhibits have been planned. The registration fee is \$5.

Premedical Chapter Installed.—The Premedical Club of the University of Miami was recently installed as the Florida Gamma Chapter of Alpha Epsilon Delta, national premedical honor society, an affiliate of the American Association for the Advancement of Science and a member of the Association of College Honor Societies. Alpha Epsilon Delta has about 7,200 members in the forty-seven chapters at colleges throughout the United States.

Announce Urology Award.—The American Urological Association offers an annual award of \$1,000 (first prize of \$500, second prize \$300 and third prize \$200) for essays on the result of clinical or laboratory research in urology. Competition is limited to urologists who have been in such specific practice for not more than five years and to residents in urology in recognized hospitals. The first prize essay will appear on the program of the forthcoming meeting of the association to be held at the Biltmore Hotel, Los Angeles, May 16-19, 1949.

Grants For Vitamin Studies.—The National Vitamin Foundation, 150 Broadway, New York, will award grants-in-aid, totaling \$16,000, to Western Reserve University School of Medicine, Cleveland; University of Vermont College of Medicine, Burlington; Massachusetts Institute of Technology, Cambridge, and the University of Southern California School of Medicine, Los Angeles. Among the investigations to be undertaken are the nutritional status of school children, the relationship between pyridoxine (vitamin B₆) and fat metabolism, and the effects of time elements on the utilization of water-soluble vitamins.

Pediatric Conference.—A postgraduate conference in pediatrics will be held November 8-13 at the University of Texas Medical Branch, Galveston, under the auspices of the University of Texas Child Health Program and in cooperation with the Maternal Child Health Division of the Texas State Board of Health. Among the subjects to be discussed are the newborn infant, endocrine disturbances, pediatric psychiatry, pediatric surgery and infectious diseases. Addresses will be given by the University of Texas staff members and the following guest speakers: Drs. Robert L. Jackson, Iowa City; Leo Kanner, Baltimore; J. Cyril Peterson, Nashville, Tenn.; Edith L. Potter, Chicago; Orvar Swenson, Boston, and Lewis K. Sweet, Washington, D. C.

Tuberculosis Association Maintains Culture Bank.—The National Tuberculosis Association reports that since 1946, when its Culture Bank was set up at the Trudeau Laboratory of the Trudeau Sanatorium, Trudeau, N. Y., 384 cultures had been supplied investigators in eighteen foreign countries, twenty-five states and the District of Columbia. Scientists engaged in research are being supplied with standard strains of the tubercle bacillus. Requests for cultures are filled without charge, but investigators are requested to report their research to the National Tuberculosis Association. The laboratory is part of Trudeau Foundation for the Clinical and Experimental Study of Pulmonary Diseases. Recently several strains of streptomycin-resistant tubercle bacilli have been added to the bank. Dr. Edward L. Trudeau, for whom the laboratory is named, is believed to have grown the first culture of the tubercle bacilli in this country, after Robert Koch isolated the germ in 1882. Dr. Trudeau was born one hundred years ago October 5.

Association of Blood Banks Report.—The First Annual Meeting of the American Association of Blood Banks, held in Buffalo, August 26-28, was attended by registrants representing twenty-eight states and six foreign countries. The following officers were elected. Dr. Ralph G. Stillman, New York, president; Dr. Thomas H. Seldon, Rochester, Minn., president-elect; Miss Marjorie Saunders, Dallas, Texas, secretary, and Mr. W. Quinn Jordan, Phoenix, Ariz., treasurer. The officers and directors for the eight districts, into which the country is divided, will constitute the board of directors, which will be the governing policy-making body of the association. Membership in the association is available to ethical, independently operating and policy-making, nonprofit institutions. Associate institutional memberships are also available to hospitals not having a blood bank but interested in blood banking. Individual memberships are open to all persons.

Incidence of Poliomyelitis Declines.—According to the U. S. Public Health Service, a total of 1,699 cases of poliomyelitis was reported during the week ending September 25, as compared with 1,840 (corrected figure) for the preceding week, 881 in 1947 (the five year median) and 1,425 in 1946 for the corresponding week. With a decline of 231 cases, and in view of the lateness of the season, a continued weekly decline may now be expected throughout the remainder of the year. Sharp decreases were reported in the North Central States, especially in Ohio (149 to 58), South Dakota (55 to 23) and Indiana (42 to 25). The incidence declined in California from 326 to 310. The three states which have reported more than 1,000 cases to date are California (2,982), North Carolina (2,171) and Texas (1,455). The cumulative total to September 25 is 17,653, as compared with 6,498 in 1947, 17,206 in 1946 and a five year median of 8,882 for the corresponding period. Fragmentary data from a few areas indicate, on the basis of a low case-fatality ratio, that the disease has been mild.

Dr. Stanley Awarded Franklin Medal.—Wendell M. Stanley, Ph.D., biochemist of San Francisco, will receive one of the Franklin medals of the Franklin Institute of the State of Pennsylvania "in recognition of his discovery that a virus can be a nucleoprotein rather than a living organism, thereby establishing a significant turning point in virus research; and also of his development of an effective centrifuge-type influenza vaccine by means of which the intensity of future influenza epidemics may be greatly lessened." Dr. Stanley, formerly of the Rockefeller Institute and newly appointed professor and head of the department of biochemistry at the University of California Medical School, Berkeley-San Francisco, and director of the Virus Laboratory of the University of California, received his Ph.D. degree from the University of Illinois, Chicago, 1929, and has been the recipient of a number of awards, including the \$1,000 Prize of the American Association for the Advancement of Science in 1936 and the Isaac Adler Prize of the Medical School of Harvard University, 1938; he was Nobel Laureate in Chemistry in 1946.

Nutrition Awards.—The American Institute of Nutrition will make three awards to investigators at its annual meeting next spring. The 1949 award of \$1,000 established by Mead Johnson and Company will be given to the laboratory (non-clinical) or clinical research worker in the United States or Canada who has published during 1948 the most meritorious scientific report dealing with the field of the B-complex vitamins. While the award will be given primarily for publication of specific papers, it may be recommended that it be made to a worker for contributions over an extended period. The Borden Award in Nutrition, \$1,000 and a gold medal, made available by the Borden Company Foundation, Inc., will be given in recognition of distinctive research by investigators in the United States and Canada which has emphasized the nutritive significance of the components of milk or of dairy products. The award will be made primarily for publication of specific papers. The Osborne and Mendel Award of \$1,000, established by the Nutrition Foundation, Inc., for the recognition of outstanding accomplishments in the general field of exploratory research in the science of nutrition, will be given to the investigator who is judged to have made the most significant published contribution in the year. While preference will be given to research workers in the United States and Canada, investigators in other countries are not excluded. Nominations for these awards must be in the hands of the chairman of the nominating committee by Jan. 15, 1949. They should be accompanied by such data relative to the accomplishment of the nominee and his research as will facilitate the task of the committee of judges. Nominating committee chairman for the Mead Johnson Award is Harold H. Williams, Cornell University, Ithaca, N. Y.; for the Borden Award, James M. Orten, Wayne University College of Medicine, Detroit 26, and for the Osborne and Mendel Award, D. W. Woolley, Rockefeller Institute for Medical Research, New York.

Military Surgeons Meeting.—The Association of Military Surgeons of the United States will meet at the Gunter Hotel, San Antonio, Texas, Nov. 11-13, under the presidency of Brig. General Edgar Erskine Hume, Washington, D. C. In addition to addresses by the Surgeons General among others, forum lectures will be given by:

Capt. Harold L. D. Kirkham, U.S.N.R. (Ret.), and Lt. Comdr. S. Baron Hardy, U.S.N.R., Houston, Texas, Military Use of a Cross-Leg Skin Flap.
Lt. Col. Kleinsasser, Dallas, Texas, Subphrenic and Liver Abscesses.
Lt. Col. Kenneth E. Fletcher, Randolph Field, Texas, Movement of the Sick and Wounded by Air.
Capt. Paul E. Spangler, U.S.N., Corpus Christi, Texas, Some Observations on Pilonidal Cyst.
Edward H. Cushing, Washington, D. C., Research in the Veterans Administration.
Edgar J. Poth, Galveston, Texas, Promotion of Healing Following Intestinal Surgery.
Harry Eagle, Bethesda, Md., Chemotherapeutic and Prophylactic Use of Penicillin.
Col. William J. Kennard, Washington, D. C., Aircrew Maintenance: A Problem of Aviation Preventive Medicine.
Lt. Comdr. Philip B. Phillips, U.S.N., Pensacola, Fla., The Psychiatrist in a Dispensary.
Comdr. James G. Bryson Jr., U.S.N., Corpus Christi, Texas, Ocular Manifestations in Intracranial Injury.
C. Ferd Lehmann, San Antonio, Texas, Auto-Sensitization Dermatitis.
Maj. Gen. Charles L. Williams, Bethesda, Md., Control of Murine Typhus Fever.
Col. Rufus L. Holt, Washington, D. C., Progress in Virus and Rickettsial Diseases.

Panel discussions will be given Friday afternoon.

Cancer Symposium at Annual Meeting.—A symposium will be held at the annual meeting of the American Cancer Society, Hotel Commodore, New York, November 6-7. The program is as follows:

The Cancer Problem Today: Charles S. Cameron, New York, A World Problem; John R. Heller Jr., Bethesda, Md., A National Problem; Daniel A. Blain, Washington, D. C., Are There Dangers in Lay Cancer Propaganda?; Herbert L. Lombard, Boston, Creating Awareness. Treatment—Recent Advances: Bertram V. A. Low-Beer, San Francisco, Diagnosis of Breast Tumors by Radioactive Phosphorus; John H. Lawrence, Berkeley, Calif., Treatment of Diseases of the Hematopoietic System with Artificial Radioactivity; Rulon W. Rawson, New York, Application of Radioactive Materials in the Management of Thyroid Cancer; Norman Treves, New York, Castration as a Therapeutic Agent in Cancer of the Male Breast; Ira T. Nathanson, Boston, Hormone Therapy in Cancer of the Female Breast. Lung Cancer: Theodore F. Hillish, Washington, D. C., Results of Community Wide Chest X-Ray Programs in Cancer Case Finding; John R. McDonald, Rochester, Minn., and Peter A. Herbut, Philadelphia, Cytologic Diagnosis of Cancer of the Lung; E. W. Alton Ochsner, New Orleans, Prospects of Improved Control of Lung Cancer. Cancer Research and Education and the Cancer Problem in General Medical Practice: Harry Eagle, Bethesda, Md., Progress in Cancer Research at the National Cancer Institute; Samuel C. Harvey, New Haven, Conn., Present Status and Future Plans of Cancer Education in Our Medical Schools; Maurice T. Root, West Hartford, Conn., Cancer Problems of a Family Doctor.

A summary by each chairman will be given at the end of each session, and discussion from the floor will be invited. Speakers at the dinner November 6 will be Dr. L. Henry Garland, San Francisco, "Present Potentials of Radiation Therapy," and Dr. Shields Warren, Washington, "What Can We Expect from Atomic Energy?"

CORRECTION

Dr. Wells at Anderson Hospital.—Dr. Benjamin B. Wells, formerly dean of the University of Arkansas School of Medicine, Little Rock, is director of research and head of the department of clinical pathology at the M. D. Anderson Hospital for Cancer Research at Houston, not at Galveston as was stated in THE JOURNAL, Feb. 21, p. 567. The hospital is a branch of the University of Texas and is the state cancer hospital.

Marriages

MILTON FRANCIS BROWN, Shaker Heights, Ohio, to Miss Ruth Virginia Best at New Brighton, Pa., June 27.

HERBERT MCKELDEN SMITH JR., Staunton, Va., to Miss Anne Noble Sims of Portland, Maine, July 10.

WILLIAM F. KNOFF, Syracuse, N. Y., to Miss Nancy Nettleton Edwards of Cazenovia, July 10.

JAMES W. CORRELL, Fairfield, Conn., to Miss Cynthia Cannon Hewitt in New York, August 7.

JOHN GREGG HAND to Miss Irma Virginia Gross, both of Philadelphia, September 4.

SELWYN BRODY to Mrs. Jeanne Davis Carey, both of New York, August 5.

Deaths

John Gordon Wilson * professor emeritus of otolaryngology at the Northwestern University Medical School in Chicago, died at the Putnam Memorial Hospital in Bennington, Vt., August 13, aged 81, of cerebral hemorrhage. Dr. Wilson was born in Edinburgh, Scotland, Dec. 10, 1866. He received his M.B. and C.M. degrees from the University of Edinburgh Faculty of Medicine in 1890. After studying in Vienna and Berlin he settled in Glasgow, Scotland, where he was appointed surgeon to the Bellahouston Dispensary and the dispensary of the Victoria Infirmary. In 1901 he accepted the position of instructor in the anatomy department of the University of Chicago and in 1905 became assistant professor of anatomy. In 1908 he joined the faculty of Northwestern University Medical School as professor of otology, in 1924 was named professor of otolaryngology and chairman of the department and in 1945 retired with the rank of professor emeritus. He was a past president and secretary of the Otological Research Committee, past president of the Institute of Medicine of Chicago and the American Otological Society. A specialist certified by the American Board of Otolaryngology, Dr. Wilson was a member of the American Laryngological Association and American Laryngological, Rhinological and Otological Society. He was a fellow of the American College of Surgeons, an honorary member of the Harvey Society of New York, a member of the Illinois State Medical Society, the American Association for the Advancement of Science and the National Research Council. During World War I he served as a captain in the Canadian Expeditionary Forces. He was formerly otolaryngologist on the staffs of the Passavant Memorial and Wesley Memorial hospitals in Chicago. Dr. Wilson was the author of a history of the medical schools of America in the 18th Century, and a medical history of Edinburgh University in the same period as well as of numerous other publications.

Arthur Mullin Wright * Earleville, Md.; born in Lyndonville, N. Y., in 1879; Cornell University Medical College, New York, 1905; in 1907 joined the faculty of the New York University College of Medicine as assistant in surgery, becoming clinical professor in 1916, associate professor in 1920, George David Stewart professor in 1933 and chairman of the department in 1942; retired in August 1946 with the rank of professor emeritus, after thirty-nine years of teaching; member of the Medical Society of the State of New York, New York Surgical Society, American Surgical Society, International Surgical Association and the New York Academy of Medicine; a fellow and for many years a member of the board of governors of the American College of Surgeons; specialist certified by the American Board of Surgery; an officer in the medical corps of the U. S. Army during World War I, serving as commanding officer of Base Hospital number 1, the Bellevue Unit; later attached to the French Medical Corps, for which service he was made Chevalier of the Legion of Honor of France; interned at St. Vincent's Hospital and from 1912 to 1930 was on its attending staff; for many years director of surgery at the French Hospital; joined Bellevue Hospital in 1907 and in 1927 was made director of the third surgical division, a position he held until his retirement from the hospital; served on the consulting staffs of the Doctors Hospital in New York, Mount Vernon (N. Y.) Hospital, St. Joseph's Hospital in Yonkers, St. Agnes Hospital in White Plains, St. Luke's Hospital in Newburgh, N. Y., and the Central Islip (N. Y.) State Hospital; member of the board of directors of the Union Hospital, Elkton; at a dinner held in his honor in February 1946 by alumni, students and other friends, it was announced that the dais for the auditorium of the New York University-Bellevue Medical Center would bear his name; in 1946 New York University conferred on him the honorary degree of doctor of science; died in New York June 24, aged 68.

Vivean Visscher Wood * St. Louis; born in Pettis County, Mo., in 1886; Washington University School of Medicine, St. Louis, 1912; assistant professor of otolaryngology at St. Louis University School of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Oto-Laryngology, American Laryngological Association, American Laryngological, Rhinological and Otological Society and the American Otological Society; fellow of the American College of Surgeons; served during World War I; on the staffs of the Jewish, Bethesda, De Paul and St. Luke's hospitals and Deaconess Home and Hospital; consulting otolaryngologist at St. Mary's Group of Hospitals; died in University City, Mo., June 20, aged 61, of heart disease.

Walter John Farrell * Johnson City, N. Y.; born in Chicago in 1890; Fordham University School of Medicine, New York, 1917; also a graduate in pharmacy; past president of the Broome County Medical Society; member of the American Public Health Association, New York State Health Officers Association and the Association of Military Surgeons of the United States; for many years health officer and school physician; served during World War I; on the consulting staffs of the Ideal Hospital in Endicott, N. Y., and Binghamton (N. Y.) City Hospital; affiliated with Our Lady of Lourdes Memorial Hospital in Binghamton, N. Y., and the Charles S. Wilson Memorial Hospital, where he died July 25, aged 57, of mesenteric thrombosis.

Marshall Clark Keith, Cheyenne, Wyo.; born in Carroll County, Ill., April 12, 1874; Rush Medical College, Chicago, 1896; member of the American Medical Association; for many years secretary of the Wyoming State Medical Society; formerly secretary of the Wyoming State Board of Medical Examiners and secretary and state health officer of the Wyoming Department of Public Health; for many years treasurer of the school board; served as county physician; scientific editor of the Wyoming Section of *Colorado Medicine*; author of a book of poems; affiliated with Natrona County Memorial Hospital, where he died in July, aged 74, of uremia.

Augustus William Anderson, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1943; served during World War II; formerly an intern and resident in orthopedics at the Charity Hospital, where he died July 21, aged 29, of brain tumor.

Herbert Aaron Citron, Newport, Ky.; University of Cincinnati College of Medicine, 1948; interned at the Michael Reese Hospital in Chicago; died in the Children's Hospital, Boston, July 6, aged 23, of Hodgkin's disease.

George Ingersoll Dakin, Grosse Pointe, Mich.; Michigan College of Medicine and Surgery, Detroit, 1891; died in Alexander Blain Hospital, Detroit, July 21, aged 78, of cerebral hemorrhage.

Perry Cleveland Farnell, Branford, Fla.; Medical College of the State of South Carolina, Charleston, 1912; member of the American Medical Association; died June 5, aged 63, of coronary occlusion.

Karl L. Fife, Lordsburg, N. M.; University of Colorado School of Medicine, Denver, 1935; served overseas during World War II; on the staff of the Lordsburg Hospital; died May 23, aged 45, in a glider crash.

James Surran Fleming * Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1913; served in France during World War I; past president of the Memphis Urologic Society; died July 6, aged 57.

Frederick Biggers Fox, Freeburg, Ill.; St. Louis University School of Medicine, 1906; died in St. Elizabeth's Hospital, Belleville, July 21, aged 76, of cerebral hemorrhage.

Michael Leo Gallagher, Oak Park, Ill.; Rush Medical College, Chicago, 1899; served on the staffs of various Veterans Administration hospitals; died at Downey July 14, aged 79, of coronary occlusion.

Frank Hackett Gilreath, Lexington, Va.; University of Nashville (Tenn.) Medical Department, 1898; member of the American Medical Association and the Medical Society of the State of North Carolina; died June 19, aged 79, of cardiovascular disease.

Nathan Bernard Glassman * Boston; College of Physicians and Surgeons, Boston, 1916; died June 8, aged 58, of agnogenic myeloid metaplasia.

Victor Maurice Gore * Tucson, Ariz.; Washington University School of Medicine, St. Louis, 1908; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; affiliated with the Pima County General Hospital and the St. Mary's Hospital and Sanatorium, where he died May 30, aged 63, following gastric resection for peptic ulcer.

William C. Kiser, Vale, N. C.; Southern Medical College, Atlanta, 1889; died June 20, aged 81, of heart disease.

George Albert Landes, Parsons, Kan.; Rush Medical College, Chicago, 1904; member of the American Medical Association; served during World War I; affiliated with Mercy Hospital; died June 24, aged 67, of coronary heart disease.

William Polk Longmire Sr. * Sapulpa, Okla.; Hospital College of Medicine, Louisville, 1904; formerly affiliated with the Indian Service; fellow of the American College of Surgeons; on the associate staff, Morningside Hospital, Tulsa, and consulting staff, St. John's Hospital, Tulsa; on the staff of City Hospital, where he died June 1, aged 66, of heart disease.

John MacLean, Boston, Baltimore Medical College, died with Massachusetts General Hospital and Massachusetts Hospital, where he died June 21, aged 72, of cancer.

A. Magraw, Gilman City, Mo.; Lincoln (Neb.) College of Chiropractic, 1899; died in Marion, Ind., 88.

C. Makepeace, Hackensack, N. J.; Kentucky School of Medicine, Louisville, 1901; formerly associated with the U. S. Health Service; died June 28, aged 65.

Richard Robert Mason, North Conway, N. H.; Harvard School of Medicine, 1901; member of the American Medical Association, Massachusetts Medical Society and the New England Obstetrical and Gynecological Society; fellow of the College of Surgeons; affiliated with Massachusetts Hospital and Boston City Hospital, where he died aged 72, of hypertension and arteriosclerotic heart disease.

Grant McDade, East Liverpool, Ohio; Ohio University, Columbus, 1905; died May 8, aged 75.

Under H. McLeod & Aberdeen, N. C.; Baltimore College, 1890; died June 19, aged 77.

F. McMillan, Charlevoix, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, member of the American Medical Association; served as coroner; affiliated with Charlevoix Hospital, where he died aged 69, of coronary occlusion and myocardial infarction.

Dr. A. A. J. Miller, Baltimore; Baltimore University of Medicine, 1892; formerly assistant superintendent of the public schools; died in Union Memorial Hospital aged 88, of gastric and prostatic hemorrhage.

Frederick Miller, Auburn, N. Y.; Syracuse University College of Medicine, 1897; died in St. Petersburg, Fla., aged 74.

Hugh Morgan, Wilkes-Barre, Pa.; College of Physicians and Surgeons, Baltimore, 1891; member of the American Medical Association; died May 27, aged 90, of hypostatic pneumonia and arteriosclerosis.

H. Morrison, Hartsville, Ind.; Kentucky School of Medicine, Louisville, 1893; served as county health commissioner; died in Memorial Hospital, Greensburg, June 29, aged 68, of cerebral hemorrhage.

Alph Aloysius Mullen, Houston, Texas; Jefferson Medical College of Philadelphia, 1893; member of the American Medical Association; fellow of the American College of Surgeons; died in St. Joseph's Infirmary June, aged 81, of bronchopneumonia.

James Muthart, Jermyn, Pa.; Jefferson Medical College of Philadelphia, 1906; died May 12, aged 66, of carcinoma of the right lung.

Trimble Palmer & Pine Bluff, Ark.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; two terms served on the state examining board; died in Memorial Hospital May 25, aged 69, of coronary occlusion.

Yer Paretzky & Huntington Park, Calif.; University of Moscow Faculty of Medicine, Russia, 1917; member of the Jean Trudeau Society; for many years chest clinician for Los Angeles City and Los Angeles County health departments; member of the tuberculosis division of the Los Angeles County Hospital; died May 17, aged 53.

William O. Phillips, Newburgh, Ind.; Pulte Medical College, Homopathic, Cincinnati, 1900; served during World War I; major, medical reserve corps, not on active duty; died in Pasadena, Calif., May 20, aged 69, of carcinoma of the bile duct.

Charles Felix Prairie & Massena, N. Y.; Syracuse University College of Medicine, 1906; secretary and past president of the St. Lawrence County Medical Society; served during World War I; president of the board of education; president of the Massena National Bank; on the staff of the Massena (N. Y.) Memorial Hospital and the A. Barton Hepburn Hospital in Ogdensburg, where he died June 30, aged 63, of carcinoma of the lower esophagus.

Julian McGruder Robinson, Danville, Va.; University College of Medicine, Richmond, 1899; member of the American Medical Association and the Southern Surgical Association; fellow of the American College of Surgeons; affiliated with Memorial Hospital; died June 28, aged 73.

Thomas Bell Rodham, Scranton, Pa.; Medico-Chirurgical College of Philadelphia, 1897; died June 15, aged 80, of cerebral hemorrhage.

John Christian Serkland, Rothsay, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; member of the American Medical Association; served on the board of education and as health officer and mayor of Rothsay; affiliated with St. Luke's Hospital in Fargo, N. D., where he died May 9, aged 75, of coronary thrombosis.

Eubert Verner Simons, Spring Valley, Minn.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1902; died May 27, aged 74, of cardiac failure.

Samuel Alexander Springwater & Los Angeles; Memphis (Tenn.) Hospital Medical College, 1894; member of the Illinois State Medical Society; died May 14, aged 78.

Lawrence Lorraine Stepp & Fort Lauderdale, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1917; died May 30, aged 56, of carcinoma of the lung.

Irl Thomas, Ashland, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; member of the American Medical Association; for many years affiliated with the Veterans Administration, serving on the staffs of various Veterans Administration hospitals; died in the Veterans Administration Hospital, Louisville, June 21, aged 56.

Louis Monroe Tomlinson & Harveyville, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1913; past president of the Wabaunsee County Medical Society; served overseas during World War I; died in Topeka, July 1, aged 59.

Mark La France Underwood, Little Rock, Ark.; Marion-Sims College of Medicine, St. Louis, 1898; served on the staff of the State Hospital; died May 29, aged 72, of congestive heart failure.

George Edgar Vaughan, Winnebago, Minn.; College of Physicians and Surgeons of Chicago, 1895; died in Rochester, Minn., May 31, aged 83, of calcareous aortic stenosis and hypertrophy of the prostate.

James R. Vermillion, Princeton, W. Va.; Maryland Medical College, Baltimore, 1900; member of the American Medical Association; died June 20, aged 76, of arteriosclerosis.

Jay Herbert Wallahan, Corning, Iowa; St. Louis College of Physicians and Surgeons, 1897; member of the American Medical Association; died June 4, aged 82, of cerebral hemorrhage.

Edward J. Weitenberner, Detroit; Detroit College of Medicine, 1899; died June 25, aged 71.

Francis M. Wilmer, Winfield, Kan.; College of Physicians and Surgeons of Chicago, 1896; member of the American Medical Association; died June 22, aged 77.

William David Wolfe & Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1934; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; served in New Guinea and the Philippines during World War II; affiliated with South Baltimore General and Johns Hopkins hospitals; died in Sinai Hospital June 29, aged 37, of acute monocytic leukemia.

William Vincent Woods & Indianapolis; Indiana University School of Medicine, Indianapolis, 1929; associate professor of orthopedic surgery at his alma mater; specialist certified by the American Board of Orthopaedic Surgery, Inc.; attending orthopedic surgeon to Methodist, St. Francis and St. Vincent's hospitals; died June 3, aged 45, of coronary thrombosis.

Edwin Sayre Woodyard, Pennsboro, W. Va.; Medical College of Virginia, Richmond, 1925; served in France during World War I; died June 14, aged 50, of coronary thrombosis.

Charles Clinton Yarbrough, Memphis, Tenn.; Tennessee Medical College, Knoxville, 1893; vice president of the Wayne County (Mich.) Medical Society in 1901 and 1902; died in the Memphis Eye, Ear, Nose and Throat Hospital June 11, aged 79, of cerebral hemorrhage.

Joseph R. Zicarelli, New York; Long Island College Hospital, Brooklyn, 1909; member of the American Medical Association; affiliated with New York Eye and Ear Infirmary, New York Post-Graduate Hospital and St. Vincent's Hospital, where he died June 28, aged 65.

Edgar Nelson Zinn & Fort Dodge, Iowa; Chicago College of Medicine and Surgery, 1909; also a graduate in pharmacy; past president of the Webster County Medical Society; affiliated with St. Joseph Mercy Hospital, where he died May 29, aged 61, of carcinoma of the colon.

Deaths

John Gordon Wilson * professor emeritus of otolaryngology at the Northwestern University Medical School in Chicago, died at the Putnam Memorial Hospital in Bennington, Vt., August 13, aged 81, of cerebral hemorrhage. Dr. Wilson was born in Edinburgh, Scotland, Dec. 10, 1866. He received his M.B. and C.M. degrees from the University of Edinburgh Faculty of Medicine in 1890. After studying in Vienna and Berlin he settled in Glasgow, Scotland, where he was appointed surgeon to the Bellahouston Dispensary and the dispensary of the Victoria Infirmary. In 1901 he accepted the position of instructor in the anatomy department of the University of Chicago and in 1905 became assistant professor of anatomy. In 1908 he joined the faculty of Northwestern University Medical School as professor of otology, in 1924 was named professor of otolaryngology and chairman of the department and in 1945 retired with the rank of professor emeritus. He was a past president and secretary of the Otolological Research Committee, past president of the Institute of Medicine of Chicago and the American Otolological Society. A specialist certified by the American Board of Otolaryngology, Dr. Wilson was a member of the American Laryngological Association and American Laryngological, Rhinological and Otolological Society. He was a fellow of the American College of Surgeons, an honorary member of the Harvey Society of New York, a member of the Illinois State Medical Society, the American Association for the Advancement of Science and the National Research Council. During World War I he served as a captain in the Canadian Expeditionary Forces. He was formerly otolaryngologist on the staffs of the Passavant Memorial and Wesley Memorial hospitals in Chicago. Dr. Wilson was the author of a history of the medical schools of America in the 18th Century, and a medical history of Edinburgh University in the same period as well as of numerous other publications.

Arthur Mullin Wright * Earleville, Md.; born in Lyndonville, N. Y., in 1879; Cornell University Medical College, New York, 1905; in 1907 joined the faculty of the New York University College of Medicine as assistant in surgery, becoming clinical professor in 1916, associate professor in 1920, George David Stewart professor in 1933 and chairman of the department in 1942; retired in August 1946 with the rank of professor emeritus, after thirty-nine years of teaching; member of the Medical Society of the State of New York, New York Surgical Society, American Surgical Society, International Surgical Association and the New York Academy of Medicine; a fellow and for many years a member of the board of governors of the American College of Surgeons; specialist certified by the American Board of Surgery; an officer in the medical corps of the U. S. Army during World War I, serving as commanding officer of Base Hospital number 1, the Bellevue Unit; later attached to the French Medical Corps, for which service he was made Chevalier of the Legion of Honor of France; interned at St. Vincent's Hospital and from 1912 to 1930 was on its attending staff; for many years director of surgery at the French Hospital; joined Bellevue Hospital in 1907 and in 1927 was made director of the third surgical division, a position he held until his retirement from the hospital; served on the consulting staffs of the Doctors Hospital in New York, Mount Vernon (N. Y.) Hospital, St. Joseph's Hospital in Yonkers, St. Agnes Hospital in White Plains, St. Luke's Hospital in Newburgh, N. Y., and the Central Islip (N. Y.) State Hospital; member of the board of directors of the Union Hospital, Elkhart; at a dinner held in his honor in February 1946 by alumni, students and other friends, it was announced that the dais for the auditorium of the New York University-Bellevue Medical Center would bear his name; in 1946 New York University conferred on him the honorary degree of doctor of science; died in New York June 24, aged 68.

Vivean Visscher Wood * St. Louis; born in Pettis County, Mo., in 1886; Washington University School of Medicine, St. Louis, 1912; assistant professor of otolaryngology at St. Louis University School of Medicine; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Oto-Laryngology, American Laryngological Association, American Laryngological, Rhinological and Otolological Society and the American Otolological Society; fellow of the American College of Surgeons; served during World War I; on the staffs of the Jewish, Bethesda, De Paul and St. Luke's hospitals and Deaconess Home and Hospital; consulting otolaryngologist at St. Mary's Group of Hospitals; died in University City, Mo., June 20, aged 61, of heart disease.

Walter John Farrell * Johnson City, N. Y.; born in Chicago in 1890; Fordham University School of Medicine, New York, 1917; also a graduate in pharmacy; past president of the Broome County Medical Society; member of the American Public Health Association, New York State Health Officers Association and the Association of Military Surgeons of the United States; for many years health officer and school physician; served during World War I; on the consulting staffs of the Ideal Hospital in Endicott, N. Y., and Binghamton (N. Y.) City Hospital; affiliated with Our Lady of Lourdes Memorial Hospital in Binghamton, N. Y., and the Charles S. Wilson Memorial Hospital, where he died July 25, aged 57, of mesenteric thrombosis.

Marshall Clark Keith, Cheyenne, Wyo.; born in Carroll County, Ill., April 12, 1874; Rush Medical College, Chicago, 1896; member of the American Medical Association; for many years secretary of the Wyoming State Medical Society; formerly secretary of the Wyoming State Board of Medical Examiners and secretary and state health officer of the Wyoming Department of Public Health; for many years treasurer of the school board; served as county physician; scientific editor of the Wyoming Section of *Colorado Medicine*; author of a book of poems; affiliated with Natrona County Memorial Hospital, where he died in July, aged 74, of uremia.

Augustus William Anderson, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1943; served during World War II; formerly an intern and resident in orthopedics at the Charity Hospital, where he died July 21, aged 29, of brain tumor.

Herbert Aaron Citron, Newport, Ky.; University of Cincinnati College of Medicine, 1948; interned at the Michael Reese Hospital in Chicago; died in the Children's Hospital, Boston, July 6, aged 23, of Hodgkin's disease.

George Ingersoll Dakin, Grosse Pointe, Mich.; Michigan College of Medicine and Surgery, Detroit, 1891; died in Alexander Blain Hospital, Detroit, July 21, aged 78, of cerebral hemorrhage.

Perry Cleveland Farnell, Branford, Fla.; Medical College of the State of South Carolina, Charleston, 1912; member of the American Medical Association; died June 5, aged 63, of coronary occlusion.

Karl L. Fife, Lordsburg, N. M.; University of Colorado School of Medicine, Denver, 1935; served overseas during World War II; on the staff of the Lordsburg Hospital; died May 23, aged 45, in a glider crash.

James Surran Fleming * Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1913; served in France during World War I; past president of the Memphis Urologic Society; died July 6, aged 57.

Frederick Biggers Fox, Freeburg, Ill.; St. Louis University School of Medicine, 1906; died in St. Elizabeth's Hospital, Belleville, July 21, aged 76, of cerebral hemorrhage.

Michael Leo Gallagher, Oak Park, Ill.; Rush Medical College, Chicago, 1899; served on the staffs of various Veterans Administration hospitals; died at Downey July 14, aged 79, of coronary occlusion.

Frank Hackett Gilreath, Lexington, Va.; University of Nashville (Tenn.) Medical Department, 1898; member of the American Medical Association and the Medical Society of the State of North Carolina; died June 19, aged 79, of cardiovascular disease.

Nathan Bernard Glassman * Boston; College of Physicians and Surgeons, Boston, 1916; died June 8, aged 58, of agnogenic myeloid metaplasia.

Victor Maurice Gore * Tucson, Ariz.; Washington University School of Medicine, St. Louis, 1908; member of the founders group of the American Board of Surgery; fellow of the American College of Surgeons; affiliated with the Pima County General Hospital and the St. Mary's Hospital and Sanatorium, where he died May 30, aged 63, following gastric resection for peptic ulcer.

William C. Kiser, Vale, N. C.; Southern Medical College, Atlanta, 1889; died June 20, aged 81, of heart disease.

George Albert Landes, Parsons, Kan.; Rush Medical College, Chicago, 1904; member of the American Medical Association; served during World War I; affiliated with Mercy Hospital; died June 24, aged 67, of coronary heart disease.

William Polk Longmire Sr. * Sapulpa, Okla.; Hospital College of Medicine, Louisville, 1904; formerly affiliated with the Indian Service; fellow of the American College of Surgeons; on the associate staff, Morningside Hospital, Tulsa, and consulting staff, St. John's Hospital, Tulsa; on the staff of City Hospital, where he died June 1, aged 66, of heart disease.

Hector John MacLean, Boston; Baltimore Medical College, 1908; affiliated with Massachusetts General Hospital and Massachusetts Memorial Hospital, where he died June 21, aged 72, of heart disease.

Jodia A. Magraw, Gilman City, Mo.; Lincoln (Neb.) Medical College of Cotner University, 1899; died in Macon June 18, aged 88.

Frank C. Makepeace, Hackensack, N. J.; Kentucky School of Medicine, Louisville, 1906; formerly associated with the U. S. Public Health Service; died June 28, aged 65.

Nathaniel Robert Mason, North Conway, N. H.; Harvard Medical School, Boston, 1901; member of the American Medical Association, Massachusetts Medical Society and the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; affiliated with Massachusetts General Hospital and Boston City Hospital, where he died May 3, aged 72, of hypertension and arteriosclerotic heart disease.

Willard Grant McDade, East Liverpool, Ohio; Ohio Medical University, Columbus, 1905; died May 8, aged 75.

Alexander H. McLeod † Aberdeen, N. C.; Baltimore Medical College, 1896; died June 19, aged 77.

Fraley F. McMillan, Charlevoix, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; member of the American Medical Association; served as county coroner; affiliated with Charlevoix Hospital, where he died June 29, aged 66, of coronary occlusion and myocardial infarction.

Charles A. A. J. Miller, Baltimore; Baltimore University School of Medicine, 1892; formerly assistant superintendent of Baltimore public schools; died in Union Memorial Hospital July 4, aged 88, of gastric and prostatic hemorrhage.

Albert Frederick Miller, Auburn, N. Y.; Syracuse University College of Medicine, 1897; died in St. Petersburg, Fla., June 17, aged 74.

Aston Hugh Morgan, Wilkes-Barre, Pa.; College of Physicians and Surgeons, Baltimore, 1891; member of the American Medical Association; died May 27, aged 90, of hypostatic pneumonia and arteriosclerosis.

James H. Morrison, Hartsville, Ind.; Kentucky School of Medicine, Louisville, 1893; served as county health commissioner; died in Memorial Hospital, Greensburg, June 29, aged 81, of cerebral hemorrhage.

Joseph Aloysius Mullen, Houston, Texas; Jefferson Medical College of Philadelphia, 1893; member of the American Medical Association; fellow of the American College of Surgeons; died in St. Joseph's Infirmary June, aged 81, of bronchopneumonia.

Lewis James Muthart, Jermyn, Pa.; Jefferson Medical College of Philadelphia, 1906; died May 12, aged 66, of carcinoma of the right lung.

John Trimble Palmer † Pine Bluff, Ark.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; for two terms served on the state examining board; died in Davis Hospital May 25, aged 69, of coronary occlusion.

Meyer Paretzky † Huntington Park, Calif.; University of Kharkov Faculty of Medicine, Russia, 1917; member of the American Trudeau Society; for many years chest clinician for the Los Angeles City and Los Angeles County health departments; member of the tuberculosis division of the Los Angeles General Hospital; died May 17, aged 53.

William O. Phillips, Newburgh, Ind.; Pulte Medical College, Homeopathic, Cincinnati, 1900; served during World War I; major, medical reserve corps, not on active duty; died in Altadena, Calif., May 20, aged 69, of carcinoma of the common bile duct.

Charles Felix Prairie † Massena, N. Y.; Syracuse University College of Medicine, 1906; secretary and past president of the St. Lawrence County Medical Society; served during World War I; president of the board of education; president of the Massena National Bank; on the staff of the Massena (N. Y.) Memorial Hospital and the A. Barton Hepburn Hospital in Ogdensburg, where he died June 30, aged 63, of carcinoma of the lower esophagus.

Julian McGruder Robinson, Danville, Va.; University College of Medicine, Richmond, 1899; member of the American Medical Association and the Southern Surgical Association; fellow of the American College of Surgeons; affiliated with Memorial Hospital; died June 28, aged 73.

Thomas Bell Rodham, Scranton, Pa.; Medico-Chirurgical College of Philadelphia, 1897; died June 15, aged 80, of cerebral hemorrhage.

John Christian Serkland, Rothsay, Minn.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1900; member of the American Medical Association; served on the board of education and as health officer and mayor of Rothsay; affiliated with St. Luke's Hospital in Fargo, N. D., where he died May 9, aged 75, of coronary thrombosis.

Eubert Verner Simons, Spring Valley, Minn.; Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1902; died May 27, aged 74, of cardiac failure.

Samuel Alexander Springwater † Los Angeles; Memphis (Tenn.) Hospital Medical College, 1894; member of the Illinois State Medical Society; died May 14, aged 78.

Lawrence Lorraine Stepp † Fort Lauderdale, Fla.; University of Pennsylvania School of Medicine, Philadelphia, 1917; died May 30, aged 56, of carcinoma of the lung.

Irl Thomas, Ashland, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; member of the American Medical Association; for many years affiliated with the Veterans Administration, serving on the staffs of various Veterans Administration hospitals; died in the Veterans Administration Hospital, Louisville, June 21, aged 56.

Louis Monroe Tomlinson † Harveyville, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1913; past president of the Wabunsee County Medical Society; served overseas during World War I; died in Topeka, July 1, aged 59.

Mark La France Underwood, Little Rock, Ark.; Marion-Sims College of Medicine, St. Louis, 1898; served on the staff of the State Hospital; died May 29, aged 72, of congestive heart failure.

George Edgar Vaughan, Winnebago, Minn.; College of Physicians and Surgeons of Chicago, 1895; died in Rochester, Minn., May 31, aged 83, of calcareous aortic stenosis and hypertrophy of the prostate.

James R. Vermillion, Princeton, W. Va.; Maryland Medical College, Baltimore, 1900; member of the American Medical Association; died June 20, aged 76, of arteriosclerosis.

Jay Herbert Wallahan, Corning, Iowa; St. Louis College of Physicians and Surgeons, 1897; member of the American Medical Association; died June 4, aged 82, of cerebral hemorrhage.

Edward J. Weitenberner, Detroit; Detroit College of Medicine, 1899; died June 25, aged 71.

Francis M. Wilmer, Winfield, Kan.; College of Physicians and Surgeons of Chicago, 1896; member of the American Medical Association; died June 22, aged 77.

William David Wolfe † Baltimore; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1934; specialist certified by the American Board of Dermatology and Syphilology; member of the American Academy of Dermatology and Syphilology; served in New Guinea and the Philippines during World War II; affiliated with South Baltimore General and Johns Hopkins hospitals; died in Sinai Hospital June 29, aged 37, of acute monocytic leukemia.

William Vincent Woods † Indianapolis; Indiana University School of Medicine, Indianapolis, 1929; associate professor of orthopedic surgery at his alma mater; specialist certified by the American Board of Orthopaedic Surgery, Inc.; attending orthopedic surgeon to Methodist, St. Francis and St. Vincent's hospitals; died June 3, aged 45, of coronary thrombosis.

Edwin Sayre Woodyard, Pennsboro, W. Va.; Medical College of Virginia, Richmond, 1925; served in France during World War I; died June 14, aged 50, of coronary thrombosis.

Charles Clinton Yarbrough, Memphis, Tenn.; Tennessee Medical College, Knoxville, 1893; vice president of the Wayne County (Mich.) Medical Society in 1901 and 1902; died in the Memphis Eye, Ear, Nose and Throat Hospital June 11, aged 79, of cerebral hemorrhage.

Joseph R. Zicarelli, New York; Long Island College Hospital, Brooklyn, 1909; member of the American Medical Association; affiliated with New York Eye and Ear Infirmary, New York Post-Graduate Hospital and St. Vincent's Hospital, where he died June 28, aged 65.

Edgar Nelson Zinn † Fort Dodge, Iowa; Chicago College of Medicine and Surgery, 1909; also a graduate in pharmacy; past president of the Webster County Medical Society; affiliated with St. Joseph Mercy Hospital, where he died May 29, aged 61, of carcinoma of the colon.

DENMARK

(From Our Regular Correspondent)

COPENHAGEN, Sept. 9, 1948.

The Teaching of the History of Medicine

How profoundly ignorant we all were of the history of medicine when we passed our final examinations! And what a boon it would have been if from the outset we had been equipped with that perspective and sense of proportion which only a solid grounding in this subject can give! We would have learned that what successive generations of physicians have hailed as epoch-making discoveries have been dismissed later as trifles or even as fallacies. These reflections must have been in the minds of the men who, under the auspices of the Danish manufacturing chemists, have started the publication of a new periodical, *Medicinsk Forum*. This gift to every Danish physician and chemist must not be regarded as a sly attempt on the part of wholesale manufacturing chemists to push their wares under the guise of scientific publications. This new periodical, which is to appear ten times a year, contains no advertisements. One of its editors, Dr. E. Jacobsen, is responsible for the modern side of medicine, while his co-editor, Dr. E. Gotfredsen, deals with its history. In a series of articles on the reception given to great discoveries in medicine, the reader is shown how thorny is the path of the pioneer (witness the fate of Semmelweis in connection with puerperal fever). The discovery of the stethoscope was given a more appreciative greeting and the Danes, at any rate, were quick to honor its discoverer.

The Early Treatment of Mental Disease

Dr. H. I. Schou, whose association with the Dianalund Sanatorium for Nervous Ailments has helped make his well deserved standing in Denmark as a psychiatrist, has lately made a forceful appeal to his countrymen to face what he bluntly calls a scandal. It concerns the neglect of the early rational treatment of light psychoses whose victims are neglected till they have become incurable. He is at present engaged on a statistical study of the costs to the community in 1944 and 1946 of the so-called nervous ailments. Though his study is not completed, he has already come to the conclusion that these ailments are more costly than cancer, tuberculosis, rheumatism or infantile paralysis. At present the Dianalund Sanatorium is the only institution of its kind in Denmark which provides for the treatment of incipient mental disease. With its 115 beds, it is incapable of satisfying all the needs of a country with a population of 4,500,000. To be sure, there are various other hospitals and asylums for which annexes are at present being planned for the "open" care of borderland cases of mental disease, but, with the housing problem in its present phase, the obstacles to the realization of all these plans are indeed great. What makes the situation tantalizing is that, according to Dr. Schou, between 75 and 85 per cent of all the cases of periodic depression can be cured by shock treatment in two to three months if taken in time, whereas when neglected such depression will last three to six months.

Mental Hygiene

The National Mental Hygiene Association has begun to publish a journal. The first number contains an article on "The Risk of Insanity in Denmark," in which Dr. K. H. Fremming gives a summary of a study which he has recently made of the population of the island of Bornholm. This study, carried out in the period 1938-1945, deals with the 5,500 persons who were born in Bornholm in the eighteen eighties. At the time of this investigation, all the survivors of this group were over the age of 50 and were therefore more or less beyond the range of hereditary mental diseases. Dr. Fremming found that up to the age of about 55 in 4 per cent of this cross section of a Danish community mental disease had developed. Schizophrenia accounted for 0.9 per cent and the manic-depressive diseases between 1 and 2 per cent, women in this category being twice as numerous as men. Epilepsy and mental disease due to

syphilis were about equally frequent, in each case affecting 3 out of every thousand persons. About 1 per cent of the population suffered from "psychogenic" mental disease mainly due to extraneous circumstances. More than 1 per cent were mentally defective, and at least 3 per cent were psychopathic. In other words, in the whole of Denmark there are, according to Dr. Fremming, at least 120,000 psychopathic and about 100,000 neurasthenic persons. In this last category women outnumber men in the ratio of 15 to 10. When all these categories are run into one, it will be seen that about 12 per cent of Danes are psychically abnormal or are, or have been, insane. According to a pamphlet recently issued by the National Mental Hygiene Association, every third hospital bed in Denmark is devoted to mental disease. In addition to the 11,000 mental patients in hospitals there are some 14,000 insane patients not in hospitals and some 16,000 who at some time or other have been insane. With these and other impressive statistics, the National Association appeals to the public for funds and other help in making better provision for the organized prevention and treatment of mental disease throughout Denmark.

The Clothing of Asylum Patients

The *Journal of the Danish Medical Association* has printed an exchange of views on the subject of the clothing of patients in asylums. A correspondent complains that the uniforms with which an asylum equips its patients make them look like a cross between a clown and a convict. How can they avoid an inferiority complex in this apparel when their friends come to visit them? Another correspondent, representing the authorities responsible for this state of affairs, defends it with the rather meager plea that plans for the reform of the clothing of lunatics in asylums "will be realized as soon as the clothing situation permits."

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Sept. 6, 1948.

The Rh Factor in Brazilian Cities

Drs. Mario P. de Mesquita and Vera Leite Ribeiro, of the blood bank of the Fernandes Figueira Pediatric Hospital, published a paper about the hematology of the Rio de Janeiro population, some of which have been reported in previous letters. The new paper deals with sensitization by the Rh factor and the etiology of fetal erythroblastosis. By immunizing guinea pigs with subcutaneous injections of pure stroma of red blood cells of Rhesus monkeys (*Macaca mulatta*), the writers were able to produce potent agglutinating Rh serums, proving, it appears, that the main fraction of the Rh antigen is found in the cellular stroma itself. Accordingly, the hypothesis of the exclusive passage of whole red cells through the placental barrier which has been frequently advanced to explain the production of Rh agglutinins seems unnecessary. To do this, the erythrocytes were separated, washed in isotonic sodium chloride solution and lysed in double distilled water. The stroma thus obtained was repeatedly washed until the supernatant fluid did not show any trace of albumin detectable by the Heller ring test and until the smears, prepared with the sediment and stained by the May-Grünwald-Giemsa method, did not reveal any complete red cell when examined microscopically under 1,500 diameter magnification.

The second part of the paper dealt with the immunization of guinea pigs to yield Rh antibodies; Drs. Mesquita and Ribeiro report a new technic. The inactivated serums of 25 normal adult guinea pigs, diluted to 1 to 4, was used for the agglutinating tests with 2 per cent suspensions of rhesus red cells in final dilutions from 1 to 5 to 1 to 80. The citrated blood of the monkeys was first filtrated through sterilized gauze to retain the clots, if any, and then centrifuged and washed, the centrifugation and washing being repeated several times. After each centrifugation the separated red cells were mixed with

more isotonic sodium chloride solution and transferred to another tube, the sediment containing some stroma and broken red cells being abandoned in the first tube. The washing of the red cells was continued until the supernatant fluid did not show the slightest trace of albumin. By this technic, a much higher sensibility of Rh agglutinins was disclosed at 5 C. than at 37 C., which confirms the previous findings of Diamond and Abelson. In addition, absorption tests disclosed that such enhanced sensitivity derives fundamentally from specific properties of Rh agglutinins and not from a nonspecific cold agglutination. The production of serum by the new technic is still under study before its utilization for diagnostic purposes.

While still using serums of American manufacture, the writers reported that among 220 white adults, Brazilian-born residents of Rio de Janeiro selected for blood donors at the Fernandes Figueira Hospital, the Rh factor reaction was negative in 28, or 13.2 per cent. Previous results reported recently in Brazil in similar conditions by Ottensooner and Pasqualini (São Paulo, 1934, 47 examinations), by Lacaz, Ferreira, Malone and Yahn (Rio de Janeiro, 1946, 445 examinations), again by Ottensooner and Pasqualini (São Paulo, 1947, 191 examinations) and by the present writers (Rio de Janeiro, 1947, 212 examinations) had shown negative percentages of 15.0, 14.2, 14.7 and 13.2, respectively, which gives the general average negative rate of 13.93 per cent for the combined sample of 1,115 persons from the two greatest cities of Brazil.

Treatment in 300 Cases of Tetanus

Dr. Joaquim M. Fonseca is head of a department of São Francisco de Assis Hospital, where most cases of tetanus of this city are treated. Since 1925, Dr. Fonseca has attended 300 cases of tetanus. He recently reviewed at the National Academy of Medicine the results of treatment. With more use of the specific therapy, the results began to improve, from year to year, so much so that at present 83 per cent of the patients are cured. According to the point of entrance of the infection, Dr. Fonseca classifies as "severe" the cases of tetanus of the hand, the throat, the uterus and the umbilicus and those connected with the puerperal state, particularly the ones following induced abortion. The routine treatment is based on the early use of the specific therapy with a dosage of 5,000 American units for adult and 3,000 for children.

Number of Physicians in Brazil

A recent publication of the Bureau of National Statistics disclosed the number of physicians in Brazil. According to the 1946 figures, there is an average of one physician to 2,780 inhabitants. The worst situation is that of the states of Maranhão, Piauí and Paraíba, which had less than one physician for 10,000 inhabitants. Of the 16,939 physicians engaged in professional activity in the whole country, 60.4 per cent were in the twenty largest cities with an aggregate population of more than 6,000,000. Out of 10,235 physicians practicing in the twenty largest cities, 6,264 worked in the cities of Rio de Janeiro and São Paulo, with an aggregate population of more than 3,700,000.

Dr. J. Bruno Lobo

In the last five years Dr. J. Bruno Lobo has been the radiologist of the Department of Gynecology of Rio de Janeiro University. Toward the beginning of last year he began to feel the early symptoms of radiodermatitis of the feet. With the aggravation of the illness, the case was definitively diagnosed as one of radiodermatitis. An American specialist suggested to Dr. Lobo that he go to the United States, where treatment of the disease could be done with great hope of success. But the trip and the treatment involve great expenditure of money, which young Dr. Lobo is unable to afford. The case became news through reports in the press, arousing public interest so much that the Brazilian Congress is passing legislation to appropriate the sum needed by Dr. Lobo for his treatment.

Correspondence

NEUROGENIC BLADDER OF POLIO-MYELITIS

To the Editor:—In the Aug. 14, 1948 issue of *THE JOURNAL* under "Current Medical Literature" on page 1485 is abstracted an article by W. L. Valk from the *Kansas Medical Society Journal* (49:93-136 [March] 1948), entitled "Neurogenic Bladder of Poliomyelitis." The author stated that cystometric studies on patients with this disease made during the study of poliomyelitis seen at the University of Kansas Medical Center during the 1946 epidemic had convinced him that a type of neurogenic bladder is produced by the disease and that this communication represents the first description of cystometric studies of the neurogenic bladder of poliomyelitis.

In the *Journal of Urology* for June 1936, I published a paper entitled "Urinary Complications In An Epidemic of Poliomyelitis" from the School of Medicine of the University of Southern California and the Urological Department of the Los Angeles General Hospital, based on a study of the epidemic of 1933-1934 in Los Angeles County, in which there were 1,792 cases with a positive diagnosis of poliomyelitis. Eighty per cent of these patients were hospitalized, more than half of them in the early systemic phase of the disease. The incidence of urinary complications was unusually high, and many cystometric studies were made, typical examples of which appear in the paper. Whether or not these were the first cystometrograms made for patients with poliomyelitis presenting symptoms of a neurogenic bladder is not definitely known, but certainly they antedated the work of Dr. Valk.

BURNETT W. WRIGHT, M.D., Nashville, Tenn.

FATAL REACTIONS AFTER AMINOPHYLLINE

To the Editor:—I read with great concern the article by Drs. Bresnick, Woodard and Sageman, *THE JOURNAL*, February 7, page 397, regarding fatal reactions following intravenous administration of aminophylline, and a letter on the subject by Dr. Harold Thomas Hyman in the issue of March 27, page 895. The latter believes that "the deaths are more likely explicable on the basis of 'speed shock.'" The clinicians who do a number of intravenous injections and see them being done have, certainly, a claim to have their say in the matter. I am firmly of opinion that the importance of speed shock in bringing about intravenous fatalities has been unduly exaggerated. Consider the thousands of intravenous injections given by doctors all over the world with rarely a watch before them! In India I have seen intravenous injections in a big hospital given by illiterate ward boys without a watch in their pocket. Their speed of injection can be imagined from their keen desire to finish the work speedily. Yet no fatality due to intravenous injection has ever occurred there! With due deference to all concerned, I may be allowed to say that speed shock is one of the myths that have been introduced in medicine by ambitious workers. Speed atrocities in intravenous administration must be in enormous numbers per day compared with the fatalities that are known to follow. By this, I do not desire to minimize the importance of speed in intravenous injections. Speed may cause a fatality by its effect on a weak and degenerated myocardium. But ordinarily the speed of an intravenous injection, due to the average bore of the needle used, is not of such a magnitude as to occasion death in a person whose myocardium is not too bad.

A remarkable point in these fatalities is that only certain drugs, like the mercurial diuretics and arsenicals, are notoriously associated with them. This leads one to presume that there is

something in the nature of drugs rather than in the mode of administration that is responsible for death.

Immediate deaths after intravenous injections fall under one of the following heads:

1. Stimulation of the skin by a prick may cause death by reflex inhibition of the heart. I know the case of an infant in whom a pinprick of the toe to take blood for smear examination caused death.

2. Pricking the wall of a vessel by a needle may similarly cause death. In a case, as soon as the needle pierced the vessel wall for taking blood, death ensued.

3. Injections of large amounts of pyrogens. This is probably the cause of death after injections of dextrose.

4. Chemical stimulus to the vessel wall or the endocardium causing reflex inhibition of the heart. This is probably the case in mercurial diuretics, aminophylline, epinephrine and iodine solutions.

5. Anaphylactic shock. This is of the nature of histamine shock. The death after arsenicals is perhaps due to this.

A number of unavoidable factors contribute to intravenous fatalities. Young doctors who have to do intravenous administrations in hospital practice should not feel unnecessarily disturbed and guilty if a mishap occurs. They may thus be prevented from developing "speedphobia" and "speed neurosis" while doing their work.

Poona City, Indian Dominion.

DIAGNOSIS OF TUBERCULOSIS

To the Editor:—I hope you have space to publish a letter which appeared on July 30, 1948 in the *New York Times* and which was also sent to the National Tuberculosis Association. The author, Angela Koenig (Mrs. Robert P. Koenig) of Carmel, Ind., brings up a problem which is of the utmost importance for control and the ultimate eradication of tuberculosis. The means for diagnosing pulmonary tuberculosis are abundant. Unfortunately, a considerable portion of the practicing medical profession still fail to take advantage of them. Mrs. Koenig's letter furnishes a good illustration of such failure.

The Editor
The New York Times

Dear Sir,

Two months ago, five weeks after the birth of my second baby, I was found to be suffering from "moderately advanced" pulmonary tuberculosis. I should not consider this a matter of general interest did I not feel that my experience might serve as a warning and possibly save some other mother from a similar disaster. From what we have now learned about the disease it is apparent to my husband and me that I had been displaying obvious symptoms for some months. Yet, although I had a competent general practitioner as family doctor, was under the care of a good obstetrician and had visited an ear, nose and throat specialist, these symptoms were not correctly diagnosed. I complained to all three doctors of constant tiredness and a persistent cough. In fact, I spent some weeks in bed taking that modern cure-all, penicillin, for an infected sinus, which was judged to be the cause of my cough. It now appears that each doctor thought that one of the others would have taken up with me the possibility of tuberculosis, with the result that in the end none of them mentioned it to me or suggested that I should have an X-ray. Consequently, not only has my own life been endangered, but I have unknowingly exposed my babies to the appalling risks of military tuberculosis and tuberculous meningitis.

Since my illness I have heard of many cases of women breaking down with tuberculosis immediately after childbirth. My experience, and theirs, shows that, despite the magnificent work of the National Tuberculosis Association, much remains to be done. It is not only the general public

which needs to be alerted to the dangers of tuberculosis, but the doctors themselves, and particularly the "specialists" in other branches of medicine, who tend to ignore the possibility of any illness outside their own field. In particular, I feel that the Tuberculosis Association should work to have the chest x-ray made as much a part of standard prenatal care as the blood test is now. And I would urge all prospective mothers to insist on an x-ray, for only thus can they be sure of safeguarding the health of themselves and their families at a time when they are apparently especially susceptible to the tubercle bacillus.

Yours very truly

Education of physicians who see cases of tuberculosis without recognizing them is still one of the most important responsibilities of medical teachers. Mrs. Koenig's letter is timely.

ESMOND R. LONG, M.D.,

Executive Secretary, American Trudeau Society.

Medical Economics

WHAT IS THE LEADING CAUSE OF DEATH?

NOTE.—Summary of a monograph by Frank G. Dickinson, Ph.D., and Everett L. Welker, Ph.D., Director and Associate in Mathematics of the Bureau of Medical Economic Research of the American Medical Association. The monograph has just been published as Bureau Bulletin Number 64.—Ed.

In view of the twenty-two year difference between the average ages at death from the leading "older" causes (heart, cancer, intracranial lesions of vascular origin and nephritis) and from the leading "younger" causes (accidents, pneumonia and influenza, and tuberculosis), the authors question the adequacy of numbers of deaths as the sole measure of the relative importance of the various causes. As an alternative to this traditional measure, they have developed two new measures for ranking the causes of death. These take into consideration the age at death as well as the number of deaths from each cause.

The authors call their two new measures "life years lost" and "working years lost." The number of life years lost from a given cause, say heart diseases, was obtained by multiplying the number of deaths at a given age from that cause by the life expectancy of a survivor of the same age and by then totaling the products for all ages. The unit of measure in this case is one "unrealized" year of life including the retired years as well as the productive years. The second new measure, "working years lost," is based on the working life expectancies of survivors of the same ages as the decedents. This technical term, "working life expectancy," is defined as the average number of years to be lived excluding those before the twentieth and after the sixty-fifth birthdays. The unit of measure here is one "unrealized" year of working life which includes only the working period, ages 20 to 65. Everyone below age 65 has a working life expectancy. The authors have taken a broad view of the potential economic productivity of all persons during the customary working period of life; thus their total of working years lost by death includes the "unrealized" years between ages 20 and 65 of all decedents, even housewives who are not generally classed as gainfully employed.

The authors have applied their two new measures to the seven leading causes of death in 1930, 1935, 1940 and 1945, using the voluminous data gathered and published by the National Office of Vital Statistics (Washington, D. C.). All causes other than the leading seven were grouped together under the caption "All Others," which accounted for 34 per cent of all deaths in 1930 and 26 per cent in 1945. The more complex actuarial concepts and computations involved in the two measures, and a breakdown by race and sex for 1945 only, are presented in two appendixes to the monograph.

During the fifteen year period covered by the study, the average age at death from all causes rose from 49 to 57 years—a testimonial to medical and social progress. Deaths from heart diseases increased from 19 per cent of all deaths in 1930 to 30

per cent in 1945, when "All Others" accounted for only 26 per cent. Deaths due to cancer rose from 9 to 13 per cent; accidental deaths accounted for about 7 per cent in each of the four quinquennial years. Despite the fact that heart diseases killed by far the largest number of persons each year, the authors contend that the evidence is inadequate to warrant the claim that heart diseases can be termed the leading cause of death for all purposes. They point out that the age at death is a necessary factor in gauging the loss to society resulting from the various causes. "Life years lost" and "working years lost" by death were developed as measures of this loss to society, not as measures of the infinite loss of the precious gift of life to the decedent or to the bereaved family. The Bureau hopes to make a second study using similar criteria to measure the loss to society from disability resulting from sicknesses and injuries, both fatal and nonfatal.

When applied to the leading causes of death in 1945, the two new measures produce surprising results. In that year deaths due to heart diseases destroyed 5,800,000 life years, cancer 2,900,000, accidents 2,800,000 and pneumonia 2,100,000. Deaths due to heart diseases were two and one-half times as numerous as deaths due to cancer, four and one-half times as numerous as accidental deaths and more than six times as numerous as deaths due to pneumonia. Despite the $4\frac{1}{2}$ to 1 ratio, the number of life years lost from deaths due to heart diseases was only twice the number of life years lost by accidental deaths. The explanation lies in the average ages at death in 1945—age 68 for heart and age 46 for accidents. The corresponding average future lifetime were 11 and 26 years, respectively. Thus the $4\frac{1}{2}$ to 1 lead of heart over accidents based on number of deaths was reduced to 2 to 1 when "life years lost" was the measure. The comparatively low average age at death from pneumonia in 1945 (46 years) accounted for a similar upgrading of that "younger" cause when ranked by "life years lost."

When the seven leading causes of death were ranked by "working years lost," accidents replaced heart in the number one position. In 1945, a year of nationwide gas rationing, the working years lost from accidental deaths numbered 1,750,000, while those from heart diseases numbered only 1,680,000. Pneumonia ranked third with 1,110,000 years and cancer fourth with 1,040,000 years. The breakdowns by race and sex presented in the appendix reveal that the young white male, who represents the productive and military strength of the country, was the special victim of accidents. In 1940 also, accidents were the number one destroyer of the customary working years of life; they ranked second in 1935 and third in 1930. Heart diseases were one rank below accidents in each of these four years, although the proportion of deaths from all causes which were due to heart diseases climbed from 19 to 30 per cent, while the proportion due to accidents remained at about 7 per cent. Evidently it has been a close race between these two leading causes when their relative importance is measured by working years lost, although pneumonia and tuberculosis outranked them in 1930 and pneumonia was first in 1935. Thus pneumonia has made way for accidents and heart diseases. Again the upgrading of the two "younger" causes is explained by the lower ages at death from these causes; the "unrealized" working years per death were far greater, on the average, for accidents and pneumonia than for heart and cancer. The authors note one statistic on medical progress which is of the utmost significance: in each of the four years studied, not one of the major fatal diseases of childhood was among the seven leaders.

The authors present their two new measures but do not state a preference for one over the other. They do contend that numbers of deaths in a period of declining mortality, longer life and a rapidly aging population cannot measure the loss to society from any one leading cause of death. If the retired, leisure years are a major consideration, then the authors recommend "life years lost" as the better of the two measures. If economic considerations are paramount, then the authors advise the use of their second new measure, "working years lost."

Although the natural causes of death—the physicians' problem—accounted for seven eighths and accidents for one eighth of the "working years lost" from deaths in 1945, the authors emphasize that the layman's role in prolonging life is greater than one eighth for he must be a cooperative patient and he must continue to support medical research and education if the accelerated

rate of medical progress is to be maintained. As noted, the reason for the upgrading of fatal accidents by the second measure is the average age at death from the "older" causes. The fact that these "older" causes account for an increasing proportion of all deaths is an indication of medical progress. If this progress slows down and the average age at death eventually falls, accidental deaths would have to increase sharply in number or the average age at death from accidents would have to decline if that cause were to maintain first place as a destroyer of "unrealized" working years. Actually the average age at death from accidents has increased less since 1930 (4.5 years) than that from either of the other two "younger" causes, pneumonia and tuberculosis. As the authors point out, the real story here is medical progress and not an alarming increase in accidental deaths. In this sense, accidental deaths are a reflection of medical progress mirrored by the second new measure for ranking the leading causes of death.

Physicians not in close touch with mortality statistics will find parts of this monograph, replete with tables and charts, rather difficult yet thoroughly worth while. All physicians, particularly those who plan medical research and health improvement programs and the National Safety Council, other agencies engaged in the battle of accident prevention and public officials who must plan for our nation's health will do well to study the monograph carefully. The actuarial note on zero mortality assumptions in Appendix B will doubtless interest many workers in the field of vital statistics. Actually the answer to the question, "What is the leading cause of death?" is of vital interest to every man, woman and child in America.

All in all this study is a statistician's way of recording medical and social progress. So few die at the younger ages and ultimately die of the "older" causes that the remaining pieces of "unrealized" lifetimes have become very short. The pieces of "unrealized" working lifetimes are even shorter; in fact, they are so short in the case of deaths due to heart diseases in 1940 and 1945 that when these numerous short pieces are strung out end to end they do not stretch out as far as the fewer and longer pieces representing the "unrealized" productive years destroyed by accidental deaths. During recent decades these numerous short pieces have slowly lengthened as life expectancies above middle age have increased. The fact that these pieces have not lengthened more rapidly in recent years is rejected by the authors as proof of the charge that medical science has concentrated on the young to the neglect of the old; it is harder to add one additional year of future lifetime to the schedule of a 67 year old man than to the schedule of one who is only 45. The basic fact which motivated the Bureau's study and which accounts for the results presented in the monograph is that the population has aged, reflecting the cumulative results of medical progress of the past. One strongly suspects, however, that the typical American physician, thinking about his patients one by one, will continue to prize most highly that cure which will postpone the largest number of deaths among his patients.

Medical Motion Pictures

Bilateral Thyrotomy for Carcinoma of the Larynx. 16 mm., color, silent, 500 feet (1 reel), showing time fourteen minutes (sound speed). Prepared by Joseph I. Kemler, M.D., Baltimore. Produced in 1948 by Richard D. Grill, Department of Art, University of Maryland, Baltimore. Procureable on loan from the author, 1908 Eutaw Place, Baltimore 17.

The film shows the surgical technic of a new operation devised by the author for certain cases of carcinoma of the larynx. He states the operation is indicated in chordal tumors situated in the anterior two thirds of the larynx when there is no fixation of the cords. This is a presentation of a controversial new operative procedure but gives no claims as to end results or five year cures. It leans toward conservatism in a field in which the trend is toward more radical surgery. The surgical procedure is fairly well illustrated in color, but the film is titled in black and white stock, throwing either the titles or the operative procedure out of focus during projection. The use of black and white titles and drawings with color surgical photography is not good technic. Photography is good. This production is directed strictly to the specialist in laryngology and would not be of interest to a general medical audience.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Charitable Hospitals: Liability When Delirious Patient Jumps from Window.—The plaintiff sued for damages for the death of her husband, alleged to have been caused by the negligence of the defendant hospital. From a judgment for the plaintiff, the defendant appealed to the court of appeals of Tennessee.

According to the plaintiff's evidence, when her husband was admitted to the defendant hospital about 6 o'clock one evening he was extremely ill with pneumonia, his temperature was 106 F. and he was delirious. He was placed in a bed on the third floor about 3 feet from a window. His brother stayed with him until about 9:30 p. m., and was then told that visiting hours were over and that he must leave. He left under protest, but before leaving he told the nurses that someone should stay in the room or the patient, in his delirium, would try to get out of bed. One of the nurses said "I will tie him in bed if he tries to get up; I will keep him in bed some way." A few hours later, however, he got out of bed, climbed to the nearby window and fell to his death on a concrete porch below. The nurses testified that after the patient's brother left they put up sideboards, administered "sodium luminal" (phenobarbital sodium) and put the patient into restraints, consisting of straps tying his ankles and wrists to the bed.

In testing a hospital's liability for negligence, said the court, there is no distinction in this state between one operated for private gain and one conducted as a charity. In the instant case the defendant's nurses and interns knew that the plaintiff was suffering from pneumonia, had a very high temperature and was so irrational as to want to get out of bed and leave, yet they refused to let his brother stay with him and watch him or stay to see the doctor about getting a special nurse for him. They realized the patient was in danger from his delirium, said that they would tie him if he tried to get up and, by restraints, undertook to keep him from getting out of bed and harming himself, but they failed to fasten the restraints securely or at least to see that his restraints did not come loose. Despite the danger they failed to keep someone in his room to watch him, but left him in his delirium only a step from an unfastened and unguarded window. The admitted fact is, said the court, that the restraints did come loose, which could hardly have happened if they had been properly fastened and if the nurses had continually watched to keep them fastened. We think, the court continued, that the jury could have reasonably found, as it did, that the defendant failed to exercise ordinary care and diligence.

The defendant contended, however, that the patient's act of jumping out of the window was so unusual and extraordinary that it was altogether unforeseeable, that it was only a possibility and not a probability, and that the defendant cannot be charged with negligence for not foreseeing and guarding against such an act. The court said that the majority rule holds that if the defendant's conduct created an unreasonable risk of harm to the plaintiff the defendant is liable for all the injuries within the reasonable range of such risk, whether they could have been foreseen or not. The particular harm which actually befell the patient need not have been foreseeable; it is enough that some such harm of a like general character was reasonably foreseeable as a likely result of defendant's failure to use due care to keep him in bed and to protect him against getting out of the window in his delirium. We think, the court concluded, that the jury could well have found that the patient's act was not so unusual or extraordinary as to be beyond range or reasonable expectation but that it was a thing which might reasonably have been expected to occur in view of his condition. Common experience shows that patients in such condition often jump or fall out of upper story windows of hospitals.

Finally the defendant contended that there was no evidence to show that the patient might not have died of pneumonia even if he had had no accident. There is no merit in such a contention, said the court. There was ample evidence to support the jury's finding that the patient's death was caused by the injuries he sustained in the accident. The fact that he was ill, even if it could be said he might later have died of such illness, did not prevent the defendant's negligence from being the legal or proximate cause of his death. Accordingly the judgment in favor of the plaintiff was affirmed and the hospital was held liable in damages for the patient's death.—*Spivey v. St. Thomas Hospital, 211 S. W. (2d) 450 (Tenn., 1948).*

Evidence: Physician's Qualifications to Testify Concerning Roentgenograms.—The defendant was charged with murder and convicted of manslaughter, from which conviction he appealed to the Supreme Court of Mississippi.

During the trial of the case the court admitted in evidence roentgenograms showing the course of the bullet through, and the place of its lodgment in, the head of the deceased. The defendant contended that this was reversible error because it was not shown, with sufficient certainty, that the roentgenograms were accurately made or that Dr. Butler, who explained them to the jury, had the required skill and knowledge to interpret them.

The victim was taken to the McComb City Hospital, McComb, Miss., immediately after being shot in the head with a pistol by the defendant. He lived only a short time and after his death the roentgenograms in question were taken. They were made, with the machine and instruments used in the hospital for that purpose by Dr. Moore, assisted by Dr. Butler, both professionally connected with the hospital, and were preserved as a record of the hospital. Dr. Butler graduated from the University of Tennessee Medical College in 1939 and later served an internship at Grace Hospital, Detroit. He then practiced medicine in the Marine Corps for three and a half years and had engaged in the general practice of medicine since 1941. He testified that he had never taken a technical course of study directed particularly to making or reading roentgenograms, but he had studied both subjects as a part of his medical course and his practical experience therein, both as a student and in the practice of medicine, had been extensive. He also testified that the roentgenograms in question were accurately taken and interpreted and there was no evidence to the contrary.

The Supreme Court said that the process of roentgenography is now well established as a method of securing a reliable representation of the bones of the human body and the location of growths and foreign substances in the body. They are admissible on authentication which satisfies the court that the thing or person is fairly portrayed, and the question of the competency of roentgenograms is a preliminary one addressed to the sound discretion of the court. We cannot say, the Supreme Court concluded, that the trial court erred in admitting these roentgenograms in evidence.

The question of the qualifications of Dr. Butler to interpret the roentgenograms is also one normally addressed to the sound discretion of the trial court. Any person who has by sufficient experience acquired adequate knowledge of roentgenograms and their interpretation may qualify as a witness. It is a general rule that for one to testify as an expert it is not necessary that he be infallible or possess the highest degree of skill. It is sufficient if he possesses peculiar knowledge, wisdom or information regarding the subject matter, acquired by study, investigation, observation, experience or practice, not possessed by the ordinary layman or inexperienced person. It is evident, we think, from the foregoing evidence that Dr. Butler was well qualified to interpret these roentgenograms.

The Supreme Court accordingly held that the physician had been properly qualified as an expert and that the roentgenograms had been accurately taken and interpreted. The judgment of conviction was affirmed. *Wallace v. State, 35 So. (2d) 703 (Miss., 1948).*

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1937 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

- Nomogram for Rate Correction of Q-T Interval in Electrocardiogram. M. Kassin, M. M. Schwarzschild and H. Bakst.—p. 990.

Terminal Electrocardiogram.—Stroud and Feil present 23 cases in which electrocardiograms were obtained before and during the terminal activity of the heart. The electrodes were attached to the moribund patient before clinical death. The three standard leads were obtained and also a few chest leads. Tracings were taken intermittently or continuously on lead II until the string became motionless. Several electrocardiograms were obtained during operations with patients under general anesthesia. The 23 patients ranged in age from 10 to 87 years. No definite heart disease could be found in 7 cases. In 1 of the latter sudden death was due to ventricular fibrillation, while in 3, ventricular fibrillation was but the terminal phase, occurring long after "clinical" death. The remaining 3 patients of this group showed no ventricular fibrillation. The heart slowed and then stopped abruptly. Of the 16 cases of obvious heart disease, 7 ended with ventricular fibrillation. Of the 8 patients with recent or old myocardial infarction, 4 died suddenly as a result of the abrupt onset of ventricular fibrillation, while the other 4 patients died suddenly with slowing and abrupt standstill. Fifteen of the 16 patients with diseased hearts died rapidly. In only 5 of these was death directly due to the onset of ventricular fibrillation.

Oxygenation Studies in Congenital Pulmonary Stenosis.—Gullickson and his associates say that the Blalock-Taussig operation has been performed in 14 instances of the tetralogy of Fallot at the University of Minnesota Hospitals. Physiologic studies of pulmonary oxygenation were made in 10 of these patients by means of recording oximetry, and of these 2 representative cases are presented. The studies were carried out preoperatively, during the operation and postoperatively. Two important facts were revealed. First, the rise in arterial oxygen saturation on the establishment of the systemic-pulmonary arterial shunt was practically immediate, and, second, the saturation time on administration of 100 per cent oxygen was greatly shortened after the operation. The first observation indicated that the shunt had a direct primary beneficial

effect on arterial oxygen saturation. The second would seem to show that the net effect of the operation was to increase the fraction of the total cardiac output supplying the pulmonary vascular bed. The implication from these observations is that the shunt resulted in a substantial improvement in the functional capacity of aeration of blood.

Rabies, the Physician's Dilemma.—After thirty years of practical experience, it is Sellers' belief that antirabic vaccine is not harmless and that it has caused more deaths than has rabies when given to persons only indirectly or remotely exposed. Since 1925, the Georgia Department of Public Health has furnished treatment for more than 50,000 persons, in 7 of whom treatment paralysis developed. Whereas in the material reviewed by the author the incidence of paralytic accidents was 1 in every 7,200 persons treated, other authors have reported an incidence of 1 in 3,000 cases. Of the 7 cases of treatment paralysis encountered in Georgia, 4 terminated fatally. Only 2 occurred in persons treated because they were actually bitten by rabid dogs. Five were in persons only remotely exposed, treated mainly to allay undue apprehension. Of these 5, 3 died. Five were in persons who had previously received antirabic vaccine. A study of 32 post-treatment fatalities due to rabies occurring among 50,000 persons treated in Georgia since 1925 reveals that 19, or 60 per cent, of these deaths occurred in persons bitten severely on the face. In no instance did rabies develop after superficial face wounds. The death rate per thousand treated for face bites was 7.9 per cent. The death rate per thousand treated for hand and arm bites was 0.5 per cent. Only 1 death followed bites on the lower extremities, a rate of 0.1 per thousand treated. Bites on the body also had a death rate of 0.1 per thousand treated. The author cites conditions under which antirabic treatment is advisable or contraindicated. He is convinced that it is not hydrophobia but rather rabiphobia which constitutes the major and most troublesome problem to the practicing physician and health officer. The administration of antirabic vaccine to persons actually bitten or scratched by the teeth of known or suspected rabid animals is a relatively

simple and justifiable procedure regardless of the outcome, in that the danger of the disease is far greater and more serious than any ill effects from the vaccine, but for exposures other than actual bites, the danger of treatment complications far exceeds that of either rabies or rabiphobia.

Prevention of Turnover in Hospital Personnel.—Eichentaub deplors the lack of adequate employment incentives in most hospitals and believes that this is causing excessive turnover. The hospital employee has had no economic security when sickness and old age have deprived him or her of the ability to work. Long hours of work and insufficient vacations are other outstanding causes of rapid turnover of personnel in the hospital. At the outset the employee should be shown a progress chart and told that he will be rated for such performances as quality of work, quantity of work, knowledge of job, dependability, initiative, cooperation, personality, ability to learn, attendance and judgment. At the end of ten days' employment, the personnel director should hold an interview to determine whether the employee likes the work, is becoming adjusted, gets along with the supervisor, is thoroughly familiar with the rules and regulations or feels overworked. This ten day follow-up interview is a crucial period. The next interview should be at the end of thirty days. It is important that every employee be interviewed before leaving the organization. Many leave because of some petty irritation or annoyance that can be "talked out." An important factor is recognition of the employee's work. This is one of the most powerful human incentives.

 Role of Family in Control of Tuberculosis. H. Hudson.—p. 519.

Pneumoperitoneum in Pulmonary Tuberculosis.—Trimble and his co-workers treated 407 patients with pulmonary tuberculosis by pneumoperitoneum. Three hundred and eighty-two of these, 160 men and 222 women, more than half of whom were between the ages of 21 and 40 and one fifth of whom were over 51, were analyzed according to results. In 218 patients (57 per cent) the disease became arrested, and an additional 48 (13 per cent) were definitely improved with cavity closed and three day sputum negative to concentration at weekly intervals for two months. The number of complications severe enough so that pneumoperitoneum was discontinued varied from 23 to 28, depending on the point of view. Analysis according to the extent of pulmonary disease showed that arrest occurred in 28 of the 34 patients with minimal pulmonary tuberculosis; in 107 of the 135 with moderately advanced, and in 83 of the 213 with far advanced tuberculosis. In 106 of the 223 patients with cavitation, the disease became arrested, and another 40 were defi-

nately improved. The position of the cavity within the lung, whether apical, in the midlung field or basal, made no statistically significant difference in the results obtained. In the 135 patients with moderately advanced disease, no marked difference was apparent between those with and those without cavitation; in 33 of the 45 with cavitation the disease became arrested, and in 74 of the 90 without cavitation; in the 213 cases of far advanced disease a decided difference was shown in favor of those with cavitation; in 73 of the 178 with cavitation the disease became arrested, in comparison with 10 of the 35 without cavitation. Results of pneumoperitoneum therapy in pulmonary tuberculosis complicated by pleurisy with effusion were gratifying, but were in general unsatisfactory in silicotuberculosis and not good in pulmonary tuberculosis complicated by tuberculous tracheobronchitis when compared with cases with cavity.

 Evaluation of Hemorrhadiation Therapy. F. B. Moor, R. E. Hoyt and M. G. Levine.—p. 358.

Tetanizing Current in Myasthenia Gravis.—Rudd and Cullinan believe that involved muscles in a patient with myasthenia gravis could be kept in normal tone if exercised judiciously. They report the case of a man, aged 53, who had ptosis of the right eyelid and who was supporting his mandible because of weakness of the masseter muscle. An attempt was made to increase the strength of the muscles and prevent progressive atrophy of disuse. The masseters were selected for treatment with a tetanizing current. Test results were used as a guide to determine the number of contractions to be eliminated during treatment. Improvement was noted within a week. In the fatigue tests, a greater number of contractions were produced without reaching the absolute fatigue point. After the patient had received the second treatment, ten contractions were elicited from the left masseter. Five days later in a fatigue test the number was 120. The number of contractions produced at treatment sessions between the aforementioned dates was seven. Two weeks later a fatigue test showed that the originally weaker right masseter had caught up with the left one, with 200 contractions elicited. After this test, sixty treatment contractions were given to each masseter. The patient lost the numbness on the right side of the face which had been present since the onset of the disease. A drooping from the side of the mouth, a source of considerable annoyance to the patient, had ceased. On palpitation the masseters appeared to be of normal tone. The patient stated "My face seems to be alive again." The final fatigue test was carried out on the forty-seventh day. Four hundred contractions were elicited from each masseter, an increase of approximately 400 per cent in forty-seven days. It was felt that the objective of increasing the strength of the masseter muscles had been reached.

 *Aspiration of Bone Marrow from Iliac Crest: Technical and Diagnostic Advantages versus Sternal Aspiration. M. A. Rubinstein.—p. 400.

Para-Aminobenzoic Acid in Amebiasis.—Dwork treated 12 patients with amebiasis with sodium salt of para-aminobenzoic acid, purely on an empiric basis. It was possible to evaluate the results of treatment in 9 of the 12 cases. Evidence of clinical

and laboratory arrest of the disease followed administration of sodium para-aminobenzoic acid in 4 of the 9 cases. Of the 7 patients with symptoms, all but 1 showed disappearance of or improvement in symptoms following treatment.

Aspiration of Bone Marrow from Iliac Crest.—Rubinstein shows that the aspiration of bone marrow from the iliac crest has the advantage that no serious injury can be sustained by any underlying organ. The procedure is less painful, and the patient is less apprehensive than when subjected to a puncture in the cardiac area. Puncture of the iliac crest can easily be performed at frequent intervals at both sides of the body, and is therefore suitable for serial bone marrow studies. Bone marrow cavities of the iliac crest can occasionally be used as a route of administering fluids into the general circulation. The cells of the iliac bone marrow have been studied for the past four and a half years in about 1,000 different cases showing normal and pathologic findings. In about 300 of these instances, simultaneous sternal marrow studies were also performed. In certain instances the iliac aspiration has proved of distinct diagnostic advantage, as compared with the sternal aspiration alone.

Infant Birthweight and Subsequent Development of Diabetes Mellitus.—Diabetic women frequently give birth to unusually large infants. Infants of excessive weight may be born to mothers before clinically apparent maternal diabetes mellitus develops. Kriss and Fletcher attempted to ascertain how the birthweight of an unusually large baby can be correlated with the likelihood of subsequent development of maternal diabetes. They analyzed the birthweight data on infants born to 100 women in whom diabetes mellitus later developed and on infants born to two control groups. They found that the birth of an infant weighing over 10 pounds (4,536 Gm.) may herald the development of diabetes in the mother. The average

birthweight of infants born to prediabetic mothers is greater than that of infants born to normal mothers. The period between the birth of the first abnormally large infant and the development of clinical diabetes in the mother averaged about twenty-four years, with a range of one to forty-six years. The authors have constructed a table permitting rough estimation of the accuracy with which one may predict the subsequent development of diabetes in a woman giving birth to a baby weighing in excess of ten pounds. The table shows that as the birthweight of the baby rises, the prediction accuracy increases progressively and is greater than 60 per cent when the baby weighs more than 13 pounds.

Epidemiology of Poliomyelitis.—Gordon and his associates say that in 1945 an epidemiologic study of poliomyelitis was organized in Chicago under the auspices of the Chicago Health Department. The method was to make a survey of the neighborhoods of verified cases of paralysis during which a certain number of contacts and noncontacts were selected for intensive study. Some results had been reported previously. Pools of daily stool collections from 76 persons were tested by inoculation of 2 monkeys each. Of 23 household contacts, 17 were infected as evidenced by virus in the stool. The incidence of infection in extra-household contacts was 9 of 23, and in noncontacts living in the same neighborhood, 2 of 18. None of 5 persons from nonpoliomyelitis (control) neighborhoods and 1 of 7 unclassified persons were infected. These results are interpreted as indicating that during this epidemic period contact with an infected person was the usual source of infection within the groups studied rather than any general widespread factor in the neighborhood.

Three Cases of Hodgkin's Disease with Predominantly Cutaneous Localization. L. Van der Meiren.—p. 181.

Calciferol in Lupus Vulgaris.—Ingram and Anning believe that more than 70 per cent of patients with lupus can be cured clinically in twelve to eighteen months by daily ultraviolet light baths to the whole body, combined with improved living conditions, particularly dietetic and environmental improvements. Calciferol has a striking effect on certain cases of lupus. The authors review observations on the effects of treatment with calciferol in 158 cases of lupus and 28 other cases. Four of the 158 patients with lupus have been cured and 23 have been improved, whereas in the other 131 cases the results have been negligible. Toxic effects have been observed in 30 patients, and in an additional 25 per cent gross disturbances developed in the calcium metabolism. A high percentage of those with diffusible calcium also show impaired renal function. The permanency of this damage is not known at present. In 1 child the renal function was only 40 per cent of normal thirty-four weeks after cessation of treatment with calciferol. In general, the experience of these authors with calciferol has not been very favorable. They do not believe that it will replace treatment with light in lupus and that its definite evaluation will require considerably more time. In sarcoidosis the results obtained with calciferol have been rather good, and good effects have been obtained also in erythema induratum and in scrofuloderma, but in tertiary syphilis the results were not good. The incidence of chilblains was not reduced during calciferol therapy.

Penicillin in Neurosyphilis.—Martin reviews observations on 24 patients with neurosyphilis who were treated with penicillin. This number included 8 patients with dementia paralytica, 5 with tabes, 2 with optic atrophy and 9 with meningovascular syphilis. Penicillin was given by the intramuscular route only. Sodium penicillin was used for most of the cases, and in recent times the crystalline form whenever obtainable. In the early days the total amount given in each course was 2,000,000 Oxford units. This was soon increased to 3,000,000 and then 4,000,000; for the last two years the course has been standardized at 5,000,000 units. Although he realizes that longer observation is necessary, the author concludes that penicillin alone is sufficient in most cases of neurosyphilis. Whether it is adequate for the most acute cases of general paralysis of the insane the experience of this series does not show. If, with the possible exception of such cases, the patient can be kept under observation after treatment and penicillin repeated if necessary, malaria will seldom be called for, and, if malaria is used at all, risks which were necessary before need not now be taken.

Pathology of Liver in Deaths from Thermal Burns.—Prior gives an account of the lesions seen in the livers of 35 men who died as the result of thermal burns. The nature of the cellular changes could be coupled with the topical therapy.

Those treated with tannic acid showed central lobular necrosis. Intracellular and intracytoplasmic inclusions were not found. Those treated with sulfonamide drugs showed fatty degeneration. No specific changes were found in those who received only bland treatment in the form of applications and baths of isotonic sodium chloride solution.

Rubella in Pregnancy and Stillbirths.—Swan says that the role played by rubella in the production of congenital malformations is now well known. Rubella appeared also to be associated with a high incidence of stillbirths. In 1946 the author made a survey of the cause of about a third of the stillbirths recorded in South Australia in the seven years 1939 to 1945, with special attention to the incidence of infectious diseases during pregnancy. There were 2,156 stillbirths registered from 1939 to 1945; questionnaires were sent to 1,265 of the mothers, and 760 replies were received. There were 16 instances (1 doubtful) of maternal rubella during pregnancy, and in 13 of these the infection took place during the first four months of pregnancy. Though various other infections had been contracted by these mothers in pregnancy, rubella was the only one which showed this particularly high incidence in the early months. It is suggested that rubella may be a factor in the causation of stillbirths by damaging the embryo early in pregnancy.

Maternal Measles, Mumps and Chickenpox as Cause of Congenital Anomalies.—Fox and his associates say that the reporting of congenital anomalies in babies born of pregnancies in which the mothers had had rubella has naturally raised the question whether other infectious diseases, particularly those due to a virus, may cause similar defects. All notifications of measles, mumps and chickenpox to the Milwaukee Health Department from 1942 to 1945 were examined, and as many as possible of the married women who had had these diseases were interviewed to determine the incidence of congenital anomalies among their offspring. The incidence of anomalies in this group of 665 children was 0.9 per cent. Of 33 live children born to the same number of married women who had measles, mumps or chickenpox while pregnant, 1 had a congenital anomaly. One pregnancy ended in spontaneous abortion in the second month. None of 22 children born of pregnancies complicated by mumps and none of 4 children born of pregnancies complicated by chickenpox showed congenital defects, but 1 of 7 children born of pregnancies complicated by measles had a unilateral harelip. The reports of other workers on anomalies following maternal rubella in pregnancy indicate an over-all incidence about fifteen times the expected rate of 0.9 per cent, and in the case of mothers who had had rubella in the first four months of gestation more than eighteen times the expected rate. The authors are aware that this series is too small for definite conclusions to be drawn.

Allergy in Patients with Stomach Disorders.—Fang points out that at the medical clinic of the University of Heidelberg 729 patients with gastric disturbances who had either an ulcer or severe gastritis were subjected to cutaneous tests with various types of foods. Over 60 per cent of the patients, or 441, gave positive allergic reaction to one or several foods. The substances producing cutaneous allergic reactions were, in order of decreasing frequency, meat, milk, egg yolk, barley, oats, vegetables, egg white, rye, fish and wheat. Only 29, or 17 per cent, of 170 patients without gastric disturbances gave positive reaction to the food substances. The author believes that the considerable difference in incidence of allergic reactions between the groups with and without gastric disturbances indicates a positive correlation between gastric and allergic disturbances. The relative rarity of polyvalent allergy indicates that allergy is less often a sequel than a causal factor in gastric disturbances. Allergic reaction of the gastric mucosa to the substance that had elicited positive reaction in cutaneous test was indicated by subjective symptoms in 12 of 15 cases. Other authors who studied the gastric secretion in order to ascertain an allergic reaction of the gastric mucosa did not succeed in demonstrating allergy in this way. In 8 patients with ulcers and in 7 with gastritis, the authors were able to employ desensitization to the offending substance. For two weeks the substance was eliminated from the diet, and this together with a rest cure usually improved the subjective symptoms. Then desensitization was instituted by giving twice weekly a subcutaneous injection of 0.1 cc. of a concentration of the specific allergen. The first concentration was often as low as 1:106, but in the course of five to eight injections the concentration was increased to 1:10. Then followed oral desensitization, beginning with one-half teaspoonful of the allergen (1:200) in a cup of broth, milk or gruel. The oral dose was slightly increased every day. After six weeks, 12 or 17 patients were completely free from symptoms and the others showed great improvement. The desensitization exerts no influence on psychic or other factors that may play a part in the development of the gastric disturbances.

Transvesical Prostatectomy in One Stage. K. Liavaag.—p. 828.

Prostatic Hypertrophy and Cancer of Prostate (1910-1938). A. Hvorslef.—p. 832.

Treatment of Tendinous Panarititis with One Incision, Immobilization and Penicillin Intramuscularly. I. Andersen.—p. 839.

Medical Interview and Personal Relation Between Physician and Patient.—Whitehorn stresses the importance of the physician's understanding and handling of the emotional relation between patient and physician. Through emotional reactions or psychoneuroses man himself is a biologic cause of disease. Skill and poise in interviewing enable the physician to gain an insight into the patient's personal problems and evaluate them as the cause of medical complaints or complicating factors in organic disease. In the interview, conducted not only for the purpose of acquiring information about present and earlier symptoms but also for the revelation of current attitudes, discussion of occupation and home life, is often revealing. Acquaintance with the different stages of emotional development provides the key to the understanding of personal reactions otherwise difficult to interpret and affords guidance in therapeutic strategy. The emotional relationship with the physician in which the patient may become involved, the transference

relationship, can be modified by control of the frequency, duration and intimacy of the interviews and by the patient's intercourse with other persons.

Thymol Reaction in Acute Infectious Diseases.—Iversen and Raaschou say that the thymol test, applied in 393 patients with various acute infectious diseases and in 88 normal persons, gave positive results in measles, infectious mononucleosis and hepatitis. They conclude that the thymol reaction can hardly be considered as a hepatic function test but is rather to be regarded as an expression of changes in the serum proteins due to different virus infections. Whether the changes are qualitative or quantitative is not known.

*Value of Mester's Reaction and Its Modification in Diagnosis of Rheumatic Disease. J. Puig Serrate and A. Barber Orfía.—p. 32.

*Treatment of Infantile Paralysis in Acute Period. V. Sanchis Olmos.—p. 133.

Mester's Test in Diagnosis of Rheumatic Fever.—Serrate and Barber Orfía modified Mester's test by using a 1:1,000 aqueous solution of sodium salicylate. By this modification the pain of the intradermal injection is diminished and the results of the test are as specific as those of Meyer's original test. The test is of great diagnostic value and is specific. Blood for the test is to be taken three times in both the original and the modified test, that is, before the test and again thirty and sixty minutes after it. The number of leukocytes drops after thirty and sixty minutes. The authors obtained positive results in 14 of 17 children with clinical symptoms of rheumatic disease. The test is specific even in cases in which rheumatic disease coexists with either tuberculosis or syphilis.

Treatment of Infantile Paralysis.—The number of cases of poliomyelitis seen in Spain by the author since 1941 is about 1,000. The author found that muscular spasm is independent of paralysis. It is present in all cases of poliomyelitis. Acute muscular spasm is of better prognosis for functional muscular recovery than subacute spasm. Muscular blockage or pseudoparalysis, alone in antagonistic muscles and in combination with spasm in certain antagonistic muscles, muscular incoordination in either spastic or pseudoparalytic muscles and disturbances of the peripheral structures are frequent. Kenny's treatment is of value. The technic for early and late application of warm compresses, physical therapy, manual correction of muscular deformities and muscular reeducation is described in detail. The treatment, which should be given only by physicians trained in the proper technic, prevents talipes equinus, flexion-abduction of muscles, obliquity of pelvis, scoliosis and certain aponeurotic retractions. Sequels due to destruction of motor neurons are incurable.

*Congenital Formation of Cavities of Cerebrum with Contribution to Encephalography of Porencephalous Defects in Children. H. Stech.—p. 184.

Congenital Porencephaly in Children.—Stech reports a rare case of genuine porencephaly in a girl aged 4½ years. The condition was demonstrated roentgenologically in vivo and established on necropsy. After a presumably normal birth the child was given hospital treatment for debility for three months. She never learned to speak. Because of emaciation and mental deterioration the child was readmitted to the hospital. She was apathetic and subject to convulsions. Encephalography revealed a porencephalous defect in the region of the left frontotemporal-parietal lobe triangle, communicating with the lateral ventricle and with the subarachnoid space on the same side. The defect was of Guttman's porus communicans type. Five days after the encephalography the child became lethargic, and death occurred after repeated convulsions. It is suggested that the porencephaly could have been caused by trauma to the brain during delivery. Encephalography appears to be adequate in demonstrating the lesion in doubtful cerebral disturbances.

Book Notices

Vitamins and Hormones: Advances in Research and Applications. Vol. V. Edited by Robert S. Harris, Professor of Biochemistry of Nutrition, Massachusetts Institute of Technology, Cambridge, Mass., and Kenneth V. Thimann, Professor of Plant Physiology, Harvard University, Cambridge, Mass. Cloth. Price, \$7.50. Pp. 478, with illustrations. Academic Press, Inc., 125 E. 23rd St., New York 10, 1947.

This volume is the fifth in an annual series which is serving the biochemist, physiologist and thoughtful physician by keeping him abreast of recent progress in two fields in which research is advancing with great rapidity. The discussions are detailed and have an international character, since several of the reviews have been prepared by European contributors. Although most of the principal advances in the vitamin field are adequately discussed, two reports deserve particular attention. The discussion of the physiologic availability of the vitamins by Melnick and Oser has many clinical implications and deserves attention by all concerned with problems in nutrition. The review on the physiologic effects of the pteroylglutamates in man summarizes in detail our knowledge of the actions and uses of folic acid.

The section dealing with hormones presents discussions only on selected topics. Of particular interest are the reviews on the use of androgens in women and the clinical uses of testosterone in the male. Heller and Maddock in this latter review point out that the "male climacteric" is rather infrequent and has been confused with a psychosomatic syndrome in neurotic old men. A diagnosis of the "male climacteric" should not be made without demonstration of elevated urinary gonadotropins. Testosterone therapy is of real benefit only in true androgen deficiency.

Other sections relating to hormones discuss the growth and adrenocorticotrophic hormones, the effects of exogenous estrogens on the male mammal and the biology of antithyroid agents. The reviews are all well written. The entire volume reflects care on the part of the editors. Tables, charts and illustrations are used effectively.

The Natural History of Disease. By John A. Ryle, M.A., M.D., F.R.C.P., Professor of Social Medicine in the University of Oxford. Oxford, England. Oxford Medical Publications. Second edition. Cloth. Price, \$7.50. Pp. 481, with illustrations. Oxford University Press, 114 Fifth Ave., New York 11; Amen House, Warwick Sq., London, E. C. 4, 1948.

American readers will benefit both from the style and the content of this book. In addition to a few essays on medical education in the broadest sense, there are nearly thirty chapters in which the natural history of angina, gastrointestinal syndromes, pyogenic infections and other common clinical disorders is illustrated by pithy case histories. Three new essays have been added since the first edition was published in 1936. Those on pyogenic infections have not been revised to deal with the modification of the natural history by antibiotics.

These stimulating discussions, while written by an internist and consultant, emphasize precisely those aspects of disease which are most important for the family practitioner and the young physician. Some of the therapy and clinical physiology will be strange to American readers, but the fine points of bedside and office diagnosis, the discussions of the role played by environment and personality in causing or coloring disease and the clear concise paragraphs make this a useful addition to the physician's library.

Handbook for Physicians. Loose-Leaf. Paper. Pp. 168. Commonwealth of Massachusetts, Department of Public Health, State House, Boston 33, 1947.

This is a looseleaf continuous ring binder book in paper covers which has been published annually for several years by the Health Department of the Commonwealth of Massachusetts. It contains 160 pages of information which will help doctors taking fullest advantages of the services of the Massachusetts State Department of Health, including clinics, laboratory services, hospital relationships, information about laws and regulations and numerous details of information which will help to smooth the relationship between the public health and the private practice aspects of medical service to the people of Massachusetts. Although not so classified, it constitutes an outstanding piece of practical public relations work on the part of the department.

Neurology of the Ocular Muscles. By David G. Cogan, M.D., Associate Professor of Ophthalmology, Harvard Medical School, Boston. Cloth. Price, \$6. Pp. 214, with 69 illustrations. Charles C Thomas, 301-327 E. Lawrence Ave., Springfield, Ill., 1948.

The author has made an attempt to correlate the clinical manifestations of disturbances of the ocular motor system with its neuroanatomic and neurophysiologic structure by presenting the state of the present knowledge of the clinical physiology of the ocular motor system and making clear the conclusions that can safely be drawn from the facts available. The data in this text are arranged according to objective signs rather than disease entities, as neuro-ophthalmology is concerned primarily with localization of disease and only secondarily with the nature of the underlying process. The first section of the book concerns the anatomy and physiology of the ocular muscles. The next section is on the anatomy of the nerves running to the extraocular muscles. A third section pertains to the supranuclear connections of the ocular motor system. The last two sections are concerned with the pupil and nystagmus. The chapter on nystagmus is probably the most comprehensive article on this subject in the English language. The book is profusely illustrated and contains a comprehensive bibliography of 825 references in many languages. The contents will be found of great interest to both practicing ophthalmologists and neurologists.

The 1947 Year Book of Neurology, Psychiatry and Neurosurgery. Neurology. Edited by Hans H. Reese, M.D., Professor of Neurology and Psychiatry, University of Wisconsin Medical School, Madison, Wisconsin, and Mabel G. Masten, M.D., Associate Professor of Neuropsychiatry, University of Wisconsin Medical School. Psychiatry. Edited by Nolan D. C. Lewis, M.D., Director, New York State Psychiatric Institute and Hospital, New York. Neurosurgery. Edited by Percival Bailey, M.D., Professor of Neurology and Neurological Surgery, University of Illinois. Chicago. Fabrikoid. Price, \$3.75. Pp. 702, with 115 illustrations. The Year Book Publishers, Inc., 304 S. Dearborn St., Chicago 4, 1948.

This handbook is the forty-eighth annual publication made by the Year Book Publishers. The authors are excellent clinicians, and because of this the material outlined is extremely practical and valuable. The neurologic part of this book contains 245 pages of review of most all the publications in 1947 which the authors considered important. It includes articles on anatomy, physiology and pathology, convulsive disorders and diseases of the central, peripheral and autonomic nervous systems as well as the vascular and muscular structures. Special diagnostic and therapeutic measures are discussed. The psychiatric aspect consists of 174 pages of practical psychiatry and psychoneuroses. The neurosurgical part is a relatively new addition to this handbook. It contains 221 pages of reviews of various neurosurgical papers published in 1947. This is an excellent book of reviews.

The Maryland Medical Care Program: A Report by the Staff of the Subcommittee on Medical Care, Committee on Administrative Practice, American Public Health Association. By Howard M. Kline, Ph.D., Milton Terris, M.D., Cozette Rapney and Nathan A. Kramer. Paper. Pp. 151, with illustrations. American Public Health Association, 1790 Broadway, New York, 1948.

This study is one of a series being prepared by the staff of the Subcommittee on Medical Care of the American Public Health Association. It describes critically the procedures and arrangements by which medical services are provided to the indigent and medically indigent in the state of Maryland.

Maryland has a unique system for caring for the medical needs of indigent and medically indigent persons. Instead of the usual three way division (state-city-county), the administration of a statewide program has been placed in the hands of the state department of health, with actual operation under a "bureau of medical services." This bureau is empowered to contract with physicians, dentists and hospitals for their services. To carry out this program, the Medical Care Act of 1945 provided for an advisory state council on medical care to include fourteen members representing the several professions and the official organizations directly affected by the program.

From the beginning, every effort was made to enlist the cooperation of the medical profession. A general policy of decentralization has been carried on to the extent that each county makes most of its own important decisions. Such decisions are generally made through a county committee on

medical care which includes representatives of the medical and dental societies, as well as officials of the county agencies. Patients are entitled to home, office and hospital calls and have free choice of physicians. Payments to physicians are made on a fee for service basis in accord with a fee schedule arrived at in consultation with the medical profession.

When a physician finds a patient unable to pay for services, the two together make out an application which the patient sends to the county health department. If the patient is indigent or medically indigent, certification is made by the health officer who issues an identification card to the patient. This card is presented to the physician at each call, and the physician bills the health department at the end of the month.

This report of the subcommittee provides an interesting insight into the problems which arose during the development of the Maryland medical care program. It outlines the program as it is now functioning and, in addition, provides a valuable, detailed analysis of the experience during the period from July 1945 to September 1946. The experience of the program as shown by the report seems to indicate that the means test can be applied successfully and that special provision can be made for care of the medically indigent as well as the indigent.

The only criticism voiced by the representatives of the American Public Health Association making the study is that "too many issues are resolved by requesting the faculty (medical and surgical faculty of Maryland) for advice or by urging that the county medical societies be canvassed for their recommendations." They go on to state, "To the medical members of the [advisory] Council the terms 'county advisory committee' and 'county medical society' are practically synonymous." It may well be that these are not criticisms but rather the basic reasons for the singular success of the Maryland medical care program. This study should be "must" reading for every state medical society officer interested in setting up a medical care program for the indigent and medically indigent.

Health Center Buildings. By Harry E. Handley, M.D., Assistant Director, Division of Public Health, The Commonwealth Fund. Paper. Price, 50 cents. Pp. 48, with illustrations. The Commonwealth Fund, 41 E. 57th St., New York 22, 1948.

Since 1930 the Commonwealth Fund has been concerned with the construction of eight health center buildings to house local health departments and their activities. This pamphlet presents experiences in seven of these health centers—four in Tennessee and three in Mississippi—with regard to location, space requirements, architectural design and use of the building. Nineteen pages are devoted to pictures of the health centers, together with their floor plans. Under this program it was agreed that the activities initiated during the "demonstration period" with financial assistance from the Fund would be continued with state and local tax money. A modified Georgian style was adopted by the Commonwealth architects, combining utility, fire resistance, low maintenance cost and pleasing appearance. An effort was made at each building site to take advantage of natural features. At the time each of these buildings was planned the official health service was essentially preventive and educational in character. Various local groups, interested in the educational facilities provided by the buildings, were invited to make use of them. To encourage their use by practicing physicians, the Fund made small initial contributions to several of the health centers for the purchase of medical books and magazines. In most of the areas the local medical society uses either the library or the auditorium for its meetings. In the absence of local hospitals, provision was also made for diagnostic laboratory facilities for use by the practicing physicians. From experience gained in the construction and use of these buildings definite concepts of the requirements for a health center building have been developed by the Fund staff. In view of the increase in local health centers through the Hospital Survey and Construction program of the Hill-Burton Act and the bill sponsored by the National Congress of Parents and Teachers for financing local health units, this demonstration on health centers affords basic study material for all groups interested in the extension of better health and medical service, particularly in the rural areas.

The Epithelia of Woman's Reproductive Organs: A Correlative Study of Cyclic Changes. By George N. Papanicolaou, M.D., Ph.D., Professor of Clinical Anatomy, Cornell University Medical College, New York; Herbert F. Traut, M.D., Professor of Obstetrics and Gynecology, University of California Medical School, San Francisco; and Andrew A. Marchetti, M.D., Associate Professor of Obstetrics and Gynecology, Cornell University Medical College, New York. Cloth. Price, \$10. Pp. 53, with 21 illustrations. The Commonwealth Fund, 41 E. 57th St., New York 22; Oxford University Press, Amen House, Warwick Sq., London, E. C. 4, 1948.

Here is the fundamental textbook on the Papanicolaou method for determining the presence of cancer. The book reports studies made since 1937 involving examination of the organs of 233 women and covering examination of more than 10,000 specimens. The organs concerned are the ovaries, tubes, various portions of the uterus and vagina. After a consideration of the problems involved in menstruation, chapters are devoted to the epithelium of the tissues concerned and to the cytology of various secretions and excretions. The studies are correlated with the menstrual cycle. Of greatest value in the work are a series of more than twenty magnificent colored plates and a final production indicating in color the cytology of the normal menstrual cycle. The book is invaluable for every physician who attempts this type of work.

Basic Facts of Health Education for Members of the Medical, Pharmaceutical and Nursing Professions. Selected Articles from the Ministry of Health Bulletins which have appeared in the *Pharmaceutical Journal*, 1913-1917. Boards. Price, 7s.6d. Pp. 193. The Pharmaceutical Press, 17 Bloomsbury Square, London, W.C.1, [1918].

This book is a compilation of selected items from the Bulletin of the British Ministry of Health which have appeared in *The Pharmaceutical Journal*. In 1943, the Pharmaceutical Society suggested to the Ministry of Health that means should be established so that pharmacists might obtain first hand knowledge of matters engaging the attention of the Ministry of Health. The issue of a bulletin at regular intervals was decided on, and the Pharmaceutical Society offered to publish these bulletins in its journal. The first of these appeared in January 1944 and others were published subsequently at quarterly intervals.

The fifty-two bulletins published in this volume cover a wide variety of topics starting with positive health and including such subjects as dental disease, importance of pure water, food poisoning, cancer, several on the menstrual function, a number on the common contagious diseases of childhood, dust in the home and factory, BCG vaccination, several on the venereal diseases, blood banks and plasma, and geriatrics. Each of the bulletins is brief, averaging from 3 to 4 book size printed pages. The book is well indexed. The principal interest attaching to these bulletins for American readers is the background which they give of the British attack on health education. Medical and pharmaceutical cooperation is being developed in the United States; this book may contain suggestions as to how it can be most constructively carried forward, bearing in mind differences between British and American conditions.

Tomorrow's Food: The Coming Revolution in Nutrition. By James Rorty and N. Philip Norman, M.D. Foreword by Stuart Chase. Cloth. Price, \$3.50. Pp. 258. Prentice-Hall, Inc., 70 Fifth Ave., New York 11, 1947.

Obviously Rorty's enthusiasm ran away with Dr. Norman's science. In addition to many inaccuracies this book is studded with ill founded generalizations concerning the American physician, his British colleague, the National Research Council's Food and Nutrition Board, and the Council on Foods and Nutrition of the American Medical Association.

The text of the book is concerned with a back to nature movement in nutrition with which almost all nutritionists are in accord; however, the authors fail to realize that this can be accomplished only by public education and guidance and not by ax-swinging iconoclasts.

Among some of the more blatant passages are the following: In reference to the National Health Insurance Act in Britain, "An increase of sickness among his panel patients brought no increase of income to the doctor. It meant only more work and less sleep; whereas less sickness meant more leisure for study and recreation, as well as a better chance to supplement his income by attending, on a fee for service basis, the middle class and upper class patients not covered by the Act. Hence, having thus acquired a vested interest in health, he proceeded to do something about it."

"These are the adrenal glands, than which there is no richer source of vitamin C in either animal or plant tissues." [Except green peppers, red peppers, parsnip greens, guavas, rose hips, and West Indian cherries, to mention but a few.]

"In the Mongolian idiot, the gyrus cingulum of the brain is missing. . . ." The authority in this case must be Mr. Rorty or Godey's *Lady Book*.

"Mass production of eggs—which gives us nonfertile eggs, devoid of an essential hormone."

"Homogenized milk! Can this be an oversight on the part of Divine Providence—did He forget to place an egg beater in the cow's udder?"

"All that one could be sure of was that since the food industry paid the piper, it would insist, in the end, on calling the tune. Most of the members of the Food and Nutrition Board were also connected with or dependent upon one or several of these various [industry-supported] committees and foundations. Hence when the industry supported Nutrition Foundation caught cold, the A. M. A.'s Food and Nutrition Committee sneezed; . . ."

These statements typify the book. While there is much material in this book with which no modern nutritionist would disagree, it is inextricably intermingled with nonsense and wild accusations.

British Surgical Practice. Volumes I and II. Under the General Editorship of Sir Ernest Rock Carling, F.R.C.S., F.R.C.P., Consulting Surgeon, Westminster Hospital, London, and J. Paterson Ross, M.S., F.R.C.S., Surgeon and Director of Surgical Clinical Unit, St. Bartholomew's Hospital, London. Cloth. Price, each volume, \$15; \$125, per set of 8 volumes and index. Volume I, pp. 536, with 228 illustrations. Volume II, pp. 575, with 318 illustrations. C. V. Mosby Co., 3207 Washington Blvd., St. Louis 3; Butterworth & Co., Ltd., 4-5 Bell Yard, Temple Bar, London, W. C. 2, 1947 (Volume I) and 1948 (Volume II).

These are the first two volumes of an eight volume survey of surgical practice in Great Britain. The editors state in the introduction that this is not intended for the experts. Nor is it intended for the medical student. Primarily, it is a thoroughly practical review of British surgery designed for surgeons with limited access to libraries. Under the supervision of the editors an imposing roster of contributors have compiled these volumes. A simple straightforward account of each subject has successfully eliminated the often cumbersome erudition which frequently characterizes overseas expositions of surgical material. The arrangement of contents is encyclopedic.

Each author is an authority in his field and the material is presented in matter of fact style. Marginal annotations, paragraphic headings and pre-chapter outlines render the information readily accessible. Suitable references are appended to each chapter. Those familiar with previous publications in the field of surgery emanating from England will recognize a distinct superiority in this enterprise. There is an absence of the usual deadwood and little use of vague eponymic terms. It was a little surprising to run across a rather fulsome description of Sclavo's serum for anthrax, although penicillin was somewhat cautiously recommended instead.

The books are amply illustrated. It is difficult to recommend their purchase in this country where medical libraries and medical literature are widely distributed. An undertaking of this type is expensive and subsequent revisions to keep pace with rapidly expanding fields of medicine and surgery may render the project a poor investment. However, the purpose thus far seems to be satisfactorily accomplished.

Human Neuroanatomy. By Oliver S. Strong and Adolph Elwyn, Associate Professor of Neuroanatomy, College of Physicians and Surgeons, Columbia University, New York. Second edition. Cloth. Price, \$8. Pp. 442, with 336 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Aves., Baltimore 2, 1948.

A review of the first edition of this excellent textbook was published in *THE JOURNAL* in 1943, in volume 122, p. 1214. A chapter on peripheral and segmental innervation has been added, which, curiously enough, starts with the second cervical but says not a word about the cranial nerves. The other major change is a much enlarged chapter on cerebral circulation. It is gratifying to encounter, among other things, the veins of Trolard and Labbé in a student's textbook. There is a tendency to make revisions less thorough than they might be. One can only hope that future editions will include allusion

to the work of J. Z. Young or P. Weiss on nerve fibers, to that of Caspersson and his school on the cytochemistry of the nerve cell and to that of Snider and others on the cerebellum. Even as it is, the reader will find this book with its well selected and carefully prepared bibliography highly useful and instructive.

Textbook of Gynecology. By Emil Novak, M.D., F.A.C.S., Assistant Professor of Gynecology. The Johns Hopkins Medical School, Baltimore. Third edition. Cloth. Price, \$8. Pp. 742, with 484 illustrations. Williams & Wilkins Co., Mount Royal and Guilford Ave., Baltimore 2, 1948.

The first edition of this book bore the title "Gynecology and Female Endocrinology" and, whereas the second and this edition do not include "Female Endocrinology" in the title, this subject still forms a large and important part of the book. As in the previous editions the author does not discuss operative procedures but takes up the anatomy and physiology of the pelvic organs and the diagnosis, pathology and treatment of practically all gynecologic conditions which are encountered. Throughout the book there is evidence of the author's vast experience as a gynecologist, endocrinologist, pathologist and teacher. The discussions are in simple language and the advice given is practical and conservative. The illustrations are abundant, beautiful and instructive. Many new ones have been added in this edition. The bibliography at the end of each chapter is limited to the best articles on the subject under discussion. The publishers should omit from their advertisement on the jacket the following sentence, "The references are chiefly to those publications most worth while, most recent and written in English." Novak properly lists many important papers which were published in the German language, and some of them were written long ago but are nevertheless of great value even today. The excellent chapter on "Common Disorders of the Female Urinary Organs" by Houston S. Everett is retained with revisions in the book. This edition like the previous ones, should prove to be most popular and helpful to students and general practitioners because the author has produced a splendid book and the publishers also have done their part admirably.

Modern Clinical Psychiatry. By Arthur P. Noyes, M.D., Superintendent, Norristown State Hospital, Norristown, Pennsylvania. Third edition. Cloth. Price, \$6. Pp. 525. W. B. Saunders Co., 218 W. Washington Sq., Philadelphia 5, 1948.

The present volume represents the third edition of Dr. Noyes' textbook of modern psychiatry. Probably the principal criticism of this work is the repeated introduction of theoretic concepts that have proved themselves inaccurate and therefore worthless. A sound school of psychiatry is the school which attempts to understand and reconstruct the dynamic mechanisms underlying personality development, both normal and abnormal. Apparently Dr. Noyes is not in complete agreement with this concept. One wishes that he had been more specific in presenting modern progress as developed during and since the last war. With the exception of the foregoing criticisms this is a good textbook. There is a reasonably good bibliography which the student is urged to use.

El electrocardiograma en la hipertensión arterial. Por Eduardo Joaquín Canabal. Tesis de doctorado. Prologado por Paul D. White. Epilogado por Rigmund H. Smithwick, profesor de cirugía, Boston University School of Medicine, Boston. Paper. Pp. 213, with 31 illustrations. El Ateneo, Florida 340, Córdoba 2099, Buenos Aires, 1947.

This thesis, appearing as a monograph, represents the work done by the author during his stay in Boston on the service of Dr. Paul D. White, who writes the foreword, and of Dr. R. H. Smithwick, who has written an addendum presenting his point of view on the value of surgery in essential hypertension. The author considers the electrocardiogram in hypertension first from the historical point of view and describes the present state of knowledge, as regards both standard and precordial leads. The electrocardiographic changes occurring postoperatively after the Smithwick operation are compared with those occurring spontaneously. An addendum is presented as to the theory of V limb leads. Much of the material in this monograph has appeared in earlier publications in English, but it is useful to have it all collected in one volume in Spanish. There are English summaries at the end of each of the seven chapters.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

BEE STING PROPHYLAXIS

To the Editor:—A girl patient aged 5, is sensitive to bee stings. She has been stung only twice, but these were both severe episodes. She became unconscious and cyanotic within sixty seconds after the sting. The first time she was unconscious about thirty minutes; the second about two hours. She was in extreme shock. What can be done to protect this child from bee stings? M. A. Skillington, M.D., Glendive, Mont.

ANSWER:—For immediate relief of this child from the symptoms of bee sting a hypodermic injection of 1:1,000 epinephrine, 0.2 cc., should be efficacious. If necessary, 0.5 cc. of epinephrine may be held under the tongue, in lieu of injection, care being taken not to swallow any of the drug. Antihistaminic drugs, such as diphenhydramine, triphenylamine or "neo-antergan" (N-[p-methoxybenzyl]-N,N'-dimethyl-N- α -pyridylethylene-diamine) may be given orally as a substitute if epinephrine is not available. In case of shock, strychnine, 1/120 to 1/100 grain (0.5 to 0.6 mg.), is the ideal relief medicament given hypodermically.

The main concern, however, is prophylaxis. This consists of hypodermic injections of aqueous or isotonic sodium chloride extracts of the ground whole body of the bee in suitable and ascending dosage. The extract can readily be prepared in any good laboratory. A proper bulk of ether-killed honey bees, e.g., 1 ounce (28 Gm.), is shaken up thoroughly with ether to remove pollen adhering to the bees' bodies, and then dried. It is then ground in a fine food grinder, and a definite weight, for instance, 5.0 Gm., is mixed with 50.0 cc. of equal parts glycerine and isotonic sodium chloride solution. After standing in the refrigerator over night the extract is filtered off through a Berkfeld or Seitz filter, to insure sterility, and labeled "bee extract 1:50 by weight-volume." Sterile glassware must of course be used throughout.

Further dilutions should be made in sterile isotonic sodium chloride solution by adding 0.5 cc. of the 1:50 extract to 9.5 cc. of sterile isotonic sodium chloride solution, giving a 1:1,000 extract by weight-volume. In the same way a 1:10,000 dilution may be prepared, by adding 1.0 cc. of the 1:1,000 extract to 9.0 cc. of isotonic sodium chloride solution. In like manner a 1:100,000 and a 1:1,000,000 dilution may be prepared.

Testing the patient may then be started by injecting 0.02 cc. of the 1:1,000,000 dilution on the flexor surface of the patient's arm intradermally. The immediate or twenty minute wheal should be noted, if any, and the twenty-four hour reaction, consisting usually of erythema. If neither of these is large enough to be significant, a similar injection may be given of 0.02 cc. of 1:100,000 dilution; and if no significant reaction is obtained, the 1:10,000 extract may be tried the next day. As soon as a significant immediate wheal or a noteworthy twenty-four hour erythema is observed, increasing doses may be given every other day until the dosage of the dilution concerned reaches 1.0 cc. A good schedule for this purpose is 0.05 cc., 0.10 cc., 0.2 cc., 0.3 cc., 0.4 cc., 0.6 cc., 0.8 cc., 1.0 cc. After that the successive higher concentrations may be employed similarly. In any case, 1.0 cc. of 1:1,000 extract should be adequate. When this dosage has been attained, it is usually advisable to discontinue treatment. Another suitable course of inoculations can be given at a later time if the patient encounters further trouble. In most cases, however, it has been found that the result is not only satisfactory from the point of view of protection, but is even permanent over a period of years.

Almost any bee keeper will be glad to furnish a small quantity of bees as an accommodation. A further precaution, however, is essential. The patient should be carefully tested for all of the prevailing pollens in his environment. Otherwise, he may be getting additional sensitization phenomena from pollen adhering abundantly to the bees' bodies and not entirely washed off by the ether. It is of course desirable, in addition, to have a general allergic testing by one familiar with allergenic technic.

PETROLEUM ASH

To the Editor:—What is the occupational hazard involved in cleaning out boilers fired by oil, using a vacuum apparatus? My patient does this for about six months every year. His chief complaint is a bad taste in the mouth and copious expectoration. He is 40 years old and also under treatment for duodenal ulcer.

Stephen Ivanoff, M.D., Stony Point, N. Y.

ANSWER:—The prospect of substantial damage from the residue of oil-burning furnaces is not great. In some respects such residue is similar to the fly ash from coal-burning furnaces. Fuel oils have widely scattered origins, and, correspondingly, some diversity in chemical constituency may be expected. The statements to follow definitely do not apply to all fuel oil residues. In any ash some silicates are present and at least traces of silica are expectable. Since silicates, with the exception of asbestos, are comparatively harmless, and since the content of silica is minor, no pneumoconiosis other than benign may be anticipated even though great dustiness exists. Some fuel oils are reputed to yield an ash with a significant content of vanadium, a harmful metal. Should dust inhalation lead to vanadium poisoning, the commoner manifestations would be anemia, loss of weight, inflammation of the respiratory tract, dry cough followed by bleeding, diarrhea or constipation, renal complications and "neuritic" manifestations. It may be observed that these manifestations are shared by other diseases and their occurrence is not pathognomonic of vanadium poisoning. Without forecasting any probability of vanadium poisoning from the occupation mentioned, note is made of one outstanding publication on that topic: Wyers, H.: Some Toxic Effects of Vanadium Pentoxide, *British Journal of Industrial Medicine*, 3:177, 1946. Occasionally in trades similar to the one mentioned mercury poisoning arises. The mention of marked ptialism and foul mouth tastes suggest mercury poisoning. Among other features of that disease, the following occur: sore mouth, bleeding gums, ptialism, discolored gums, gastroenteric ailments, foul or metallic breath, sleeplessness, melancholia, a peculiar eczema, speech difficulties, amnesia, mercurial excitement and anxiety. Since the American Standard Association's upper limit of the tolerable is only 1 mg. in the day's intake of air, any content of mercury compounds in oil ash becomes noteworthy. While mercury poisoning in the trade mentioned is certainly not common, the symptoms indicated call for further exploration.

POLAR BEAR LIVER

To the Editor:—In several Survival Manuals published by the Armed Services it is stated that the livers of both the polar bear and the bearded seal are poisonous. I have not been able to learn what the type of poison is or whether this is an actual fact. Can you give me information or references on this subject? Is it possible that excessively high vitamin D content of the liver might cause illness?

Charles H. Morhouse, M.D., Randolph Field, Tex.

ANSWER:—Although it has been generally recognized that eating of polar bear liver by men and dogs usually causes severe illness, some Arctic investigators have tended to be skeptical in this regard. It has also been reported that the liver of the bearded seal is poisonous, and the opinion on this point is even less unanimous.

However, the work of K. Rodahl and T. Moore in 1939-1940, which appeared in *Biochemical Journal* (37:166, 1943), indicates that the toxicity is due to the high concentration of vitamin A contained in the polar bear and bearded seal liver, and the ingestion of more than small amounts of liver results in hypervitaminosis A. Reference is also made to an account by J. K. Douth, which appeared in the *Journal of Mammalogy* (21:356-357, 1940).

COFFEE GROUND EMESIS

To the Editor:—As an anesthetist I have noted on several occasions the vomiting of coffee ground fluid in the immediate postoperative period. None of the operations were related to the stomach. The cases were usually appendectomies and the pathology not that of acute appendicitis. What is the significance of such postoperative coffee ground emesis?

Saul Dworkin, M.D., St. Louis.

ANSWER:—Duodenal ulcer, gastric ulcer or varicosities might, under certain circumstances, cause signs and symptoms leading to a diagnosis of appendicitis. Excoriations of the mucosa of the upper respiratory or digestive tract might result in swallowing of blood. Partially digested clots of blood mixed with other material in the stomach often give a characteristic "coffee ground" appearance to vomitus. There is no significance to the observations cited other than that blood or a similar substance had probably entered the stomach some time before vomiting occurred.

SUDDEN DEATH

To the Editor:—Recently a man, aged 50, died suddenly during an exciting episode while engaged in a game of cards. I had examined him about one year ago because of missed heart beats, which occurred particularly in excitement. His physical examination, including determination of blood pressure and electrocardiogram, did not reveal any abnormality. I therefore assured him that this symptom had no particular meaning, to disregard it, and prescribed a mild sedative. Since the heart standstill was caused, in all probability, by the same mechanism which caused the missed beats, could this death possibly have been prevented if I had placed this man on minimal doses of quinidine to maintain normal sinus rhythm? Might not a good many of the sudden deaths due to cardiac diseases be similar to this one, and, if so, would it not be good practice to administer quinidine in all cases of recurrent arrhythmias, as protection against such an incident? What plan and dosage should be followed?

M.D., New Jersey.

ANSWER:—Most persons who die suddenly and unexpectedly have cardiovascular disease. In a recent postmortem study of 2,030 such cases in the Borough of Manhattan, New York City, in 45 per cent death was attributed to diseases of the heart and aorta (Rabson, S. M., and Halpern, M.: Sudden and Unexpected Natural Death, *Am. Heart J.* 35:635 [April] 1948).

The exact mechanism of death in the patient mentioned is of course uncertain—it may have been cardiac standstill or ventricular fibrillation. Quinidine sulfate in doses of 3 grains (0.19 Gm.) three times daily is usually effective in lessening cardiac irritability and perhaps is often life saving in preventing fatal ventricular fibrillation. For this reason protective doses are often employed during the first few weeks following myocardial infarction. Quinidine might have prevented a fatal arrhythmia in the patient cited, if such was the mechanism of his death.

No mention is made of a postmortem examination, but cardiovascular disease existed notwithstanding the normal physical examination and electrocardiogram.

PERNICIOUS ANEMIA

To the Editor:—A woman aged 38 has had pernicious anemia for the past ten years. Three months ago she noticed numbness and paresthesia of the right mid thigh about the size of a saucer. She had been taking liver extract, with vitamin B capsules irregularly. She resumed the usual dosage during the latter month. The red cell count is now 3,400,000 with a color index of plus 1. The paresthesia extends from the right hip to the knee. In addition to liver extract she is receiving folic acid. Should liver extract be given by injection even if she exhibited a marked local reaction to it previously or are capsules sufficient? What is the significance of a gingivitis in this case? Is it considered contributory to the pernicious anemia or a result of it as so many dentists claim?

M.D., West Virginia.

ANSWER:—It is questionable whether the unilateral numbness in the thigh is a neural manifestation of the pernicious anemia. If there is a relationship, this symptom should improve with adequate liver therapy. Concentrated liver extract, 15 units per cubic centimeter, given parenterally every two or three weeks, is the treatment of choice in pernicious anemia.

If the local reaction occurred with an extract of hog liver, a trial should be given with beef liver extract (Lederle). Patients often lose their sensitivity to liver given parenterally if the injections are discontinued for a few months. During this time, remission may be maintained with an oral preparation of liver, 1 to 2 units daily or with 10 to 20 mg. of folic acid daily. As folic acid does not prevent the progression of cord damage, patients receiving this therapy should be observed closely for the appearance or increase of symptoms and signs referable to the nervous system.

The chronic gingivitis in this patient probably is unrelated to the pernicious anemia.

PREGNANCY TESTS

To the Editor:—What is present opinion regarding the use of rats as compared to rabbits in testing for pregnancy? What method prevails in the hospitals?

John Tennyson Myers, M.D., New York.

ANSWER:—Using rabbits in the Friedman test, with careful technic, and careful isolation of the animals to rule out false positive reactions, one may approach better than 92 per cent accuracy. By use of immature mice or rats in the Asheim-Zondek test, the accuracy approaches 98 per cent. Usually in the latter test, more than one animal is used.

Most hospitals use the rabbits because they are possibly easier to handle; the ear vein is used for the injection.

QUINIDINE SULFATE

To the Editor:—A 63 year old patient who had severe coronary thrombosis seven years ago has been getting along fairly well since. Recently he complains of annoying extra systoles. He now takes quinidine sulfate 3 grains (0.13 Gm.) three times daily to control this symptom. Is the continued use of quinidine harmless? Is there other medication (besides barbiturates) which can be used for control of this disagreeable symptom?

M.D., New Jersey.

ANSWER:—Quinidine sulfate is the most useful drug available for control of premature beats. Rarely hypersensitivity exists; when it is present even a single dose may result in urticaria, nausea and vomiting. Most patients tolerate the drug in the dosage mentioned without difficulty for long periods of months or years without gastrointestinal or eighth nerve symptoms. The writer is acquainted with a patient who has taken quinidine sulfate in this dosage almost constantly for fifteen years. Occasionally it is mildly laxative but appears to be otherwise harmless.

Other than sedatives and the omission of caffeine and tobacco, few drugs are of special value in this connection except quinidine (or quinine). Occasionally in patients with more troublesome cardiac irritability and paroxysmal auricular tachycardia, digitalis or squill has helped when quinidine has failed.

"HAPAMINE"

To the Editor:—Are there cases on record of injections of "hapamine" causing a flare-up of rheumatoid arthritis? A 27 year old male patient without history of rheumatism was given penicillin mist and "hapamine" for sinusitis. On his fifth injection of "hapamine" pain and swelling developed in one knee. On his sixth injection, three days later, he developed hot swollen joints in one leg, high grade fever, general malaise and tenderness of sinuses. Could this be due to "hapamine?"

J. R. Bunch, M.D., Laramie, Wyo.

ANSWER:—"Hapamine" is a conjugate prepared by azo linkage of histamine and despeciated horse serum globulin. Reactions to this substance are possible for several reasons. In spite of the fact that for the most part the antigenic properties of the globulin in this preparation have been modified by an enzyme process, there is an occasional evidence of a specific reaction in a horse serum sensitive person. Such a reaction would show itself by symptoms occurring within a few minutes to a few hours and consisting of one or more of the following manifestations: urticaria and angioneurotic edema, rhinitis, asthma, anaphylactic shock and other possible effects. Serum sickness type of reactions, consisting of urticarias, pains in the joints and fever, and occurring several days after the injection, are also possible. In addition, "hapamine" may act as a purely nonspecific protein and may produce such effects as described. A closer approximation could be made of the possible role of "hapamine" in the reaction under discussion if the chronologic details were given more fully. From the evidence at hand the reaction could be either coincidental or due to "hapamine." The possibility of a reaction to penicillin mist cannot be entirely ignored.

CATAPLEXY

To the Editor:—In *The Journal*, volume 137, page 118, May 3, 1948, appeared an inquiry concerning a "woman aged 27, who began to have periods of excessive weakness during periods of laughter." The inquirer asked about diagnosis and treatment. The answer as given is somewhat incomplete and inaccurate for the following four reasons: 1. The attacks are correctly classified as cataplexy and it is correctly stated that it is allied with narcolepsy. But the most important feature of this syndrome, attacks of sleep, which gives to it the name of narcolepsy, is not mentioned. Cases of monosymptomatic cataplexy are very rare and such patients should be carefully investigated also for the presence of concomitant narcoleptic attacks. 2. The answer states that cataplexy "is an organic condition due to a structural lesion in the corpora striata." It is generally assumed, however, that the site of the lesion in narcolepsy is the hypothalamic region, and not the corpora striata. 3. Administration of "benzedrine" for the attacks of cataplexy is recommended in the answer. But "benzedrine" is beneficial in narcoleptic and has little or no influence in cataplectic attacks. Potassium chloride should be recommended for the latter, 30 to 75 grains daily by mouth (Dynes, J. B.: *Cataplexy and Its Treatment*, *J. Nerv. & Ment. Dis.* 98:48, 1943). 4. Only 20 per cent of all cases of narcolepsy—in any form—are assumed to be postencephalitic. The statement as given in the answer that "cataplexy frequently follows an attack of epidemic encephalitis" appears doubtful therefore.

Robert Wartenberg, M.D., San Francisco.

COMMENT:—The hypothalamus is, of course, involved and so are the corpora striata. The use of potassium chloride is still in an experimental stage.—Ed.

DIETARY TREATMENT OF CIRRHOSIS OF THE LIVER

Results in One Hundred and Twenty-Four Patients Observed
During a Ten Year Period

ARTHUR J. PATEK JR., M.D.

JOSEPH POST, M.D.

OSCAR D. RATNOFF, M.D.

HAROLD MANKIN, M.D.

and

ROBERT W. HILLMAN, M.D.

New York

The present report is an analysis of results obtained in the treatment of 124 patients with cirrhosis of the liver by means of a diet rich in protein and supplemented by concentrates of the vitamin B complex. In 1937 a preliminary statement¹ was made concerning favorable therapeutic results obtained in 13 patients who had been observed during the course of one year. The improvement appeared to exceed chance expectations. A more comprehensive report² in 1941 was made on 54 patients that had been studied over a four year period. The results tended to confirm the preliminary impression. With the new dietary regimen roughly one half of the patients showed signs of significant clinical improvement. These results were considerably better than those observed in a control series of 386 patients. However, since cirrhosis of the liver is a chronic disease and since its clinical course may vary considerably in different patients, the study was extended further in order to get a larger body of evidence and to get a clearer picture of the long term results of this therapeutic program.

RATIONALE OF TREATMENT

The rationale of treatment was based on clinical and experimental observations that have been described in previous papers.³ In brief, the frequency of dietary deficiency in patients with Laennec's cirrhosis suggested that there might be an analogy between the occurrence of "alcoholic" cirrhosis and that of "alcoholic" beriberi or pellagra. It seemed possible that malnutrition itself might play an important contributory role. The prevalence of cirrhosis in countries where nutritional deficiencies were endemic added further weight to this hypothesis.

2. Patek, A. J., Jr., and Post, J.: Treatment of Cirrhosis of the Liver by a Nutritious Diet and Supplements Rich in Vitamin B Complex. *J. Clin. Investigation* **20**: 481, 1941.

3. Patek,¹ Patek and Post,² Patek, A. J., Jr.: An Evaluation of Dietary Factors in the Treatment of 'Laennec's Cirrhosis' of the Liver. *J. Mt. Sinai Hosp.* **14**: 1, 1947.

Subsequent studies on laboratory animals by a number of different workers (notably György, Webster, Blumberg, Sebrell, Rich, Himsworth, Gillman and their associates) have firmly established the concept that dietary factors may play a significant part in the pathogenesis of this disease.

METHOD AND MATERIAL

In the past ten years approximately 160 patients with cirrhosis of the liver have been treated, of whom 124 were in the stage of hepatic failure. The present report deals with the latter group. The term failure is applied to the status of those patients who have had recent hematemesis or who show signs of ascites or jaundice in addition to other evidence of hepatic insufficiency, such as wasting, fever, gastrointestinal disturbances and changes in laboratory tests indicating hepatic dysfunction. The chief symptoms and signs and their percentage incidence are listed in tables 1 and 2, together with a similar tabulation of data for 386 patients with cirrhosis of the liver who served as a control group. The control group was composed of patients with cirrhosis who had been admitted to five New York hospitals during the years 1920 to 1940.⁴ The latter patients received bed rest, supportive care and diuretics, but no specific dietary measures other than a diet high in carbohydrate, low in protein and low in fat, which was in vogue during that period.

The patients being studied were transferred to the Columbia University Research Service from the wards of municipal and voluntary hospitals, and in the main they came from lower income groups. Many were transferred because they had not responded to treatment. They represent possibly a more refractory group than those entering a general hospital for the first time because of hepatic failure. Others were referred by hospital staffs aware of our interest in this disease. A degree of selectivity may have been introduced, in that patients who were considered critically ill generally would not be transferred. Nevertheless, 7 patients died within two weeks and 23 died within one month of entry.

Data showing the symptoms and signs of hepatic failure indicate fair agreement between the treated and control series of patients. It is assumed, therefore, that the severity of the underlying disease process was comparable in the two groups. In instances in which the incidence of certain symptoms and signs is higher in the treated series, the difference may be ascribed in part to more detailed case histories and prolonged study in the treated series. Likewise, such features as fever, vascular spiders, subclinical icterus and signs of specific malnutrition usually were disregarded or ignored in the control series.

4. Ratnoff, O. D., and Patek, A. J., Jr.: The Natural History of Laennec's Cirrhosis of the Liver, *Medicine* **21**: 207, 1942.

Evidence of malnutrition was noteworthy. Ninety-one patients (73 per cent) had subsisted on poor diets, deficient particularly in meat and dairy products. In 89 per cent of these patients there was significant loss of weight, and in 36 per cent there was polyneuritis. Atrophy of the tongue papillae, dry scaly skin and macrocytic anemia were frequent observations.

* Average age 48.8 years.

† Average age 50 years.

‡ Data obtained in 99 cases.

§ Includes cases of hematemesis and those in which the disease was demonstrated by roentgenologic studies or at autopsy.

|| Diagnosis restricted to those with both motor and sensory changes.

The diagnosis of cirrhosis of the liver was based on clinical observations alone in 51 cases (41 per cent), established by biopsy or by autopsy in 73 cases (59 per cent). Differentiation is not made in the tabulation (table 1) between patients with Laennec's cirrhosis and those with the postnecrotic type (coarsely nodular toxic cirrhosis), since this distinction was not made in the control series. In 15 instances, cirrhosis was presumed to be of the postnecrotic type. In 7 of these, the diagnosis was confirmed at autopsy. If additional cases of postnecrotic cirrhosis occurred in this series they were probably few.

Program of Treatment.—On admission to the hospital the patient accepts bed rest without protest. He is usually mentally dulled, weak and distended with ascites. Fever and low grade jaundice frequently are present. With improvement, he asks for more freedom and he is allowed to be semiambulatory. Since hospitalization may require months, strict bed rest is not enforced for more than one half of the day.

Chief emphasis is placed on the diet, a detailed scheme of which appeared in a previous report.² In contrast to the traditional American diet prescribed for hepatic disease, which was high in carbohydrate but low in protein and fat, the present diet is rich in protein and ample in carbohydrate and fat. It contains 140 Gm. of protein,⁵ 365 Gm. of carbohydrate and 175 Gm.

of fat—a total of about 3,500 calories. The diet consists chiefly of meat, milk, eggs, fruit and green vegetables. Eggs are served with breakfast; meat, fish or poultry is served at dinner and supper; milk is served three times with meals and twice between meals, with 25 Gm. of yeast, in the form of milknog. If the patient eats these foods, considered basic to the program, the remainder of the diet is largely a matter of choice. The charting of the estimated food intake for each meal (1 to 4 plus) provides a stimulus to the patient and serves as a useful record. In certain cases a semisolid diet² is indicated, and in a few, when the patient is drowsy or stuporous, a regimen of liquids is prescribed.⁶ Yeast is fed in graded increasing dosage until 25 Gm. are fed twice daily. For patients who do not tolerate yeast (because of distention, diarrhea or nausea) an orally administered B complex preparation⁷ is substituted. Thiamine hydrochloride (5 mg. daily) and unconcentrated liver extract (5 cc. twice weekly) are injected intramuscularly. If the patient shows signs of severe polyneuritis or of mental confusion thiamine hydrochloride (100 mg.) and nicotinamide (300 mg.) are administered daily parenterally.

Patients with ascites are allowed fluids up to 2,000 cc. daily or somewhat more in hot weather. Salt is moderately restricted by excluding its use in the preparation of food or on the tray. Abdominal fluid is tapped before the patient is greatly distended, since distention seriously curtails the appetite. Mercurophylline injection (2 cc.) is given once or twice weekly and is combined with the daily oral administration of 4 to 6 Gm. of ammonium chloride in enteric coated pills. Alcohol is interdicted. Since the patient seldom has much desire for alcohol when he is ill with cirrhosis and since he should abstain from drinking liquor after his discharge, there appears to be no purpose in permitting its use in the hospital.

The arts of nursing and dietetics are challenged by the problem of feeding a patient to whom food is distasteful and for whom life itself frequently has little interest. He needs cajoling, sympathy and much patience. This aspect of treatment cannot be over-emphasized.

TABLE 2.—Initial Laboratory Data on 124 Patients with Cirrhosis of the Liver

	Number of Cases	Per-centage
Sulfobromophthalein sodium dye retention > 10% *..	118	100
Positive reaction to Takata Ara or flocculation test †	109	94
Serum albumin < 3.5 Gm./100 cc.....	104	90
Increased serum bilirubin.....	47	58
Average initial serum albumin 2.8 Gm./100 cc.		
Average initial serum globulin 3.6 Gm./100 cc.		
Average sulfobromophthalein sodium dye retention in 30 min. 4.9 mg./100 cc. (49%)		

* Data obtained on 118 cases; the test was not performed in 6 deeply jaundiced patients. This test measures the percentage of dye retained thirty minutes after intravenous injection of 5 mg. per kilogram of body weight.

† Data obtained on 116 cases.

In patients with cholemia, slow intravenous infusions of 10 per cent dextrose are administered, totaling 2 or 3 liters in twenty-four hours. To each liter are added 100 to 150 mg. of thiamine hydrochloride, 300 to 400 mg. of nicotinamide and 100 mg. of riboflavin.

6. Liquid diets were: (a) An eggnog mixture, consisting of 1 quart of milk to which are added 50 Gm. of dried yeast, 4 eggs, 30 Gm. of sugar and ½ teaspoon of vanilla. This is stirred vigorously and kept cold. (b) Fruit juice mixture, containing 1 quart of fresh orange juice to which are added 40 Gm. of powdered gelatin (Knox). The mixture is then stirred. These mixtures are fed on alternate hours.

7. Vitamin B complex preparations, (30 cc.) made by Lederle Laboratories, Inc., or Wyeth, Incorporated, have been fed twice daily.

5. Includes protein in dried yeast.

This regimen is discontinued when the patient is able to take oral feeding. In many cases cholemia is precipitated by hematemesis or intercurrent infection, and in these cases the precipitating condition is treated vigorously.

For the care of hematemesis, transfusion of whole citrated blood by the slow drip method is performed as soon as possible, since delay may result in irreversible collapse of the patient. Transfusion is continued as long as there is evidence of bleeding. Plasma and dextrose (10 per cent) often are given intravenously as supportive measures. Food by mouth is withheld for two or three days. The patient is only lightly sedated, since he has a tendency to lapse into cholemia.

Intercurrent infections formerly accounted for about 25 per cent of the deaths from cirrhosis. With the advent of sulfonamide and antibiotic drugs, the dangers from infection have been sharply decreased. In the present series, sixty-four courses of sulfonamide drugs were administered to 43 patients, of whom 13 received sulfanilamide, 6 sulfapyridine, 8 sulfathiazole and 16 sulfadiazine. Pneumonia, phlebitis and cellulitis comprised the chief conditions treated. In 11 instances treatment with sulfonamide drugs was effective and may have prolonged life. Of these patients, 7 subsequently died of hepatic disease. Untoward reactions were experienced by 4 patients, 2 of whom were over 70 years of age.

Although instances have been cited⁸ of hepatic damage produced by sulfonamide drugs, the risk would seem to be justified when continued infection is the serious alternative. In this regard our experience confirms that of Peterson and his co-workers.⁹ However, since hepatic complications have not been described as the result of treatment with penicillin and other related antibiotics, these agents are generally to be preferred.

Specific Adjuvants.—The use of specific adjuvants for the treatment of cirrhosis of the liver has been reported in recent papers.¹⁰ It is difficult to evaluate effects from these agents, since in most instances the patients also received diets high in protein, similar to the diet employed in the present series. In an attempt to test these substances, 8 patients were selected the course of whose disease had become stabilized after three to twelve months of the standard dietary treatment in the hospital. They were in a state of constant

nonprogressive hepatic failure. Choline and methionine were administered, without changing the dietary regimen.

Three patients received 4 to 6 Gm. daily of choline hydrochloride for six, eight and ten months respectively; 5 patients received 3 to 4 Gm. daily of methionine for an average of three and six-tenths months. In 1 patient, who received methionine for seven months, slight clinical improvement was noted. No change was apparent in the others.

After an interval of at least three months (average period five months) subsequent trial of intravenously administered liver extract¹¹ was carried out in 6 of these patients for two to eleven months. The average weekly dosage was 37 cc. in 5 cases and 200 cc. in the sixth case. In 3 of the patients the intravenous administration of liver extract was associated with gain in appetite and well-being and gradual disappearance of ascites. (These patients had received thirty-three, seventy-five and one hundred and twenty-six abdominal taps, respectively, preceding intravenous treatment with liver extract.) There was concomitant improvement in laboratory signs. Whether the improvement coincident with treatment could be ascribed to the intravenous use of liver extract could not be proved.

In 4 other patients with signs of severe hepatic failure, intravenous treatment with liver extract failed to check the unfavorable course of their disease. Death occurred within one to three months of the inception of treatment.

Reports^{10k,1} on the use of concentrated human serum albumin solution suggest that this substance may prove to be an effective aid in treatment of cirrhosis, particularly to alleviate ascites formation. Our own experience¹² has been limited to studies of 3 patients who received 600 to 800 Gm. each in fourteen to sixteen days. In these patients no sustained diuresis or therapeutic benefit was apparent, even though normal values for serum albumin were attained. These patients had an unusually protracted course, with ascites formation and other signs of hepatic failure. It is possible that more prolonged administration of albumin solution would have been effective.

RESULTS OF TREATMENT

Of 124 patients who entered the hospital with signs of hepatic failure, 61 have shown some evidence of clinical improvement. Their improvement fulfilled three criteria: (1) disappearance of jaundice, ascites and edema, (2) gain in weight and strength and (3) improvement in results of various tests of hepatic function. They have been further classified as "recovered" and as "partially improved." The term recovered is applied to 43 patients who regained sufficient bodily vigor to resume normal activities. Three patients in this group enjoyed good health for over five years, but later died after a relapse of their disease. Four others died of illnesses unrelated to cirrhosis.

The term partially improved is applied to 18 patients whose jaundice, ascites and edema completely disappeared, but whose over-all improvement was inadequate for one of three reasons: (1) they failed to regain normal bodily vigor; (2) results of tests of hepatic function showed only slight improvement after treatment, or (3) their improvement was not sustained.

Eleven of these patients survived from two to five years after entry to the hospital. Fourteen of the 18 patients died during the ten year period of observation. In 4 instances, death was unrelated to cirrhosis.

Perhaps the most convincing evidence for the efficacy of dietary treatment is derived from 12 patients who

Fig. 1.—The survival of life after the onset of ascites in patients with cirrhosis. Computations beyond the fifth year were not used because there are too few cases to be of statistical importance. Line A represents the treated patients (115) and line B the controls (230). The vertical line of figures shows the percentage of patients alive.

had two or more satisfactory responses to treatment after having suffered repeated relapses. Characteristically, they fell into their former habits of alcoholism and grossly poor diets. Relapses were attributable in almost every instance to failure of the patient to continue with the prescribed dietary treatment after discharge from the hospital. In effect, they reproduced the conditions of the experiment. The fact that these 12 patients responded well to the same treatment on two or more occasions suggests that improvement resulted from treatment and that it was not "spontaneous."

Nine additional patients have shown signs of clinical improvement, but they are not included in the aforementioned groupings since their follow-up period was limited to a few months.

STATISTICAL EVALUATION

The period of survival in the present series was compared with that in the control series. The duration of life from the onset of ascites formed the basis of this comparison. (The method of computation is described in a previous paper.²) The greater longevity in the present series is shown in figure 1. At the end of one year, 65 per cent of the treated patients and 39 per cent of the controls were alive; at the end of two years, 50 per cent of the treated patients and 21 per cent of the controls were alive; at the end of five years 30 per cent of the treated patients and 7 per cent of the controls were alive. The differences between the two series appear to be significant.

SIGNS OF IMPROVEMENT

In general it requires several months of treatment before significant changes occur. The first intimations of improvement are gain in appetite and the feeling of general well-being. More objective changes take place later, namely, the subsidence of fever and disappearance of jaundice, ascites and edema. Figure 2 shows the disappearance of these four signs of hepatic

failure in 61 patients who showed clinical improvement. This figure portrays the duration of the signs after entry to the hospital, and it does not include the prehospital period, during which the signs were present, usually for months. Although there is individual variation, jaundice and fever tend to disappear more rapidly than ascites and edema. In most instances these four signs disappeared within three months.

Fever.—Fever, which occurred in one-half the cases, subsided in each instance with improvement. Deferescence was one of the early signs of recovery.

Jaundice.—The duration of jaundice preceding entry could not be estimated accurately, because many patients were unobservant of this sign. Moreover, jaundice usually was of low grade and intermittent. Thirty-one of the 61 patients who improved had jaundice at entry. The time of disappearance of jaundice varied from a few weeks to three years. In 75 per cent of the cases jaundice disappeared within two months.

Ascites.—Preceding entry to the hospital the average duration of ascites was seven and nine-tenths months in 115 cases. Ninety-two patients (80 per cent) had required abdominal paracenteses, and the average number of abdominal paracenteses was three and five-tenths in these cases. In 23 patients with ascites, abdominal paracenteses had not been carried out before admission. Diuresis and disappearance of ascites occurred in 58 patients, or 50 per cent of those with ascites. Frequently the complete disappearance of ascites required months after the onset of slow diuresis.

Fig. 2.—Disappearance of signs of hepatic failure in 60 patients with cirrhosis showing improvement after entry to the hospital.

Figure 2 indicates the time when ascites was not detectable. The time varied from two weeks to three years. Of those patients who lost ascites, 70 per cent were ascites free within three months.

Edema.—In general, the disappearance of edema preceded slightly and paralleled the loss of ascites.

Gain in Weight.—Gain in weight was observed regularly with improvement. When the patient entered the

hospital with edema or ascites, the initial values were falsely elevated. With recovery there followed a decrease until a net (dry) weight was attained and thereafter a gain in weight that was referable to body tissue.

Mental Changes.—Mental changes, characterized by orientation and change of mood (especially euphoria), occurred in 38 per cent of the patients. Recovery from hepatic failure was regularly accompanied with a change in attitude and by increased mental competence. The patient became oriented and reasonable, and he acquired insight into his condition.

Epistaxes.—Epistaxes, present in 40 per cent of the patients, abated in most cases with improvement.

Hematemesis.—Hematemesis (presumably from esophageal varices) occurred in 42 cases, fatally in 22. Although approximately one half of the patients died within one year of the first hemorrhage, there were patients that survived hematemesis for a long time. In the present series 9 have survived five years or longer without recurrence of hematemesis. Since about 10 per cent of patients with cirrhosis show peptic ulcer (post mortem), it is possible that in a few of the unautopsied cases there had been hemorrhage from this cause.

Vascular Spiders.—Vascular spiders were observed in 43 of the 61 patients that improved. In 17 patients they were noted to have disappeared, but it is reasonably certain that additional instances (not noted) occurred as well.

Cholemia.—Cholemia may be defined as a stuporous state associated with and presumably due to failure of the liver. It frequently is precipitated by infection or hemorrhage. In the past this picture of mental fogging, deepening into stupor and coma, almost invariably was a prelude to death. Yet, in the present series, 3 patients recovered from stupor and 3 from coma, and they survived for periods of months or years thereafter. In 4 other patients responses of several days or weeks were followed by fatal relapses. However, in 19 instances of cholemia treatment was of no avail.

Our experience tends to confirm the observations of Snell and Butt,¹³ who reported that dramatic recovery from cholemia may be achieved in certain cases by infusions of dextrose supplemented with large doses of thiamine hydrochloride and nicotinamide. That intravenously administered dextrose alone may have been an important factor is suggested by earlier observations by Jones.¹⁴

Amenorrhea.—There were 7 women of menstrual age among the 61 patients who improved. Six of these had observed amenorrhea, lasting from four months to two years. In all 6 patients there was return of normal menstruation coincident with other clinical changes previously described.

Polynuritis.—When polynuritis was present, there was almost invariable recovery from paresthesia, motor weakness and atrophy, but frequently there was little change in results of objective tests, such as vibratory sensation and tendon reflexes, despite many months of intensive treatment with thiamine hydrochloride and liver extract.

Results of Laboratory Tests.—In general the correlation between results of laboratory tests and the clinical course of the disease was only fair. There may be considerable lag before the tests reflect clinical changes. Indeed, results in certain tests, such as the test with sulfobromophthalein sodium, may remain unaltered for years despite sustained clinical recovery.

In our experience the value of serum albumin has corresponded more closely to the clinical changes than other criteria employed and thus has served as a fairly dependable guide to prognosis. When the serum albumin increased to a value of over 4.0 Gm. per hundred cubic centimeters and remained at that level, the patient showed other signs of recovery. The inability to achieve this value was seen usually in patients who failed or who made only partial improvement. The mean value for serum albumin before treatment was 2.8 Gm. per hundred cubic centimeters, and after treatment it was 4.2 Gm. in the 61 patients who improved.

Changes in serum globulin were erratic and consequently less helpful as laboratory aids. The mean initial value was 3.6 Gm. per hundred cubic centimeters and the mean value after treatment was 3.2 Gm. per hundred cubic centimeters in the 61 patients who improved.

In all instances the initial result in the test with sulfobromophthalein sodium showed increased dye retention. In 40 of the 61 patients showing improvement there was a significant decrease in dye retention, and in 9 the dye retention fell to within normal limits after treatment (i. e., less than 10 per cent at one-half hour). In 21 cases there was slight decrease or no decrease in dye retention, despite other signs indicating improvement.

Results of initial Takata-Ara or cephalin flocculation tests were positive in 53 of 61 patients who improved. In 5 instances the results were negative at entry, and in 3 others the data were inconclusive. In 21 instances the results became negative coincident with improvement.

Other tests, such as tests of serum vitamin A and carotene, galactose tolerance (intravenous), urine urobilinogen excretion, serum cholesterol and cholesterol esters and plasma prothrombin time, have been performed on selected groups of patients. These tests of hepatic function also reflect, in a crude fashion, the clinical status of the disease. The first three have been the subject of other reports.¹⁵ Since the tests were not carried out in the entire series, the results are not discussed in this paper.

Pathologic Changes.—There was poor correlation between the clinical course of cirrhosis and the gross or microscopic observations in the liver. The limited data obtained from this series suggest that clinical recovery seldom is accompanied with significant anatomic changes. The livers of 15 patients showed advanced cirrhosis in biopsies during the period of clinical improvement. Advanced cirrhosis also was found post mortem in 9 patients who previously had made partial "clinical recovery" and in 2 patients who had made "clinical recovery" but died of extrahepatic disease.

In 2 patients with severe decompensation, biopsies showed slight fatty changes several years after their

Med.* 32: 397, 1947.

recovery. Minimal changes were seen in 3 others who died of extrahepatic causes after making clinical recovery from cirrhosis. Thus, there were 5 cases in which histologic improvement might have taken place.

Serial biopsies were made only in a few instances. Although such information is desirable, it should be pointed out that the histologic picture may vary considerably in different areas of the cirrhotic liver and that biopsies obtained from different sites may not be strictly comparable.

FAILURE OF TREATMENT

Of 124 patients who entered with signs of hepatic failure, 54 showed no response to treatment. In many instances they were too ill to cooperate in the dietary program. It is possible that some of these patients had too little functioning hepatic tissue to respond to any mode of treatment. Seven patients died within two weeks and 23 within one month of entry.

In certain cases intercurrent infection or hemorrhage from ruptured esophageal varices proved to be more than these debilitated patients could withstand. There were 16 who died from infection and 22 from gastro-

being 43 years. Malnutrition was not conspicuous in this group. Only 1 patient drank alcohol to excess. The interval between antecedent hepatitis or jaundice and the onset of hepatic failure varied from six months to twelve years. During this interval some had shown persistent jaundice or other signs of hepatic injury, whereas in others the disease seemed to be latent. Despite vigorous dietary treatment, only 2 patients showed temporary remissions after the onset of hepatic failure. In brief, the younger age group, equal sex ratio, lack of malnutrition and the poor response to dietary therapy were features that suggested clinical differences from Laennec's cirrhosis. Although this group is too small to be of statistical importance, it may be well to keep in mind a possible clinical distinction between Laennec's cirrhosis and postnecrotic cirrhosis.

COMMENT

The present studies indicate that Laennec's cirrhosis is not of necessity a progressive disease, since the process appears to be arrested in a significant number of patients. Improvement in symptoms and signs of the disease and increased period of survival are effected by a highly nutritious diet, rich in protein and supplemented with vitamin B concentrates. These observations have been substantiated in other reports,¹⁶ some of which describe more favorable results with the added use of specific substances.

An appraisal of different therapeutic programs is difficult, because recent series of cases are not strictly comparable to those studied in the past. Modern methods for combating shock and hemorrhage, antibiotic drugs and longer periods of hospitalization doubtless modify the course of the disease. Thus, the relative effectiveness of different therapeutic programs may involve nondietary factors.

In statistical comparisons it is essential that large numbers be employed and that the case material be similar in kind. It is self evident that the most favorable results will be obtained when treatment is instituted at an early stage of hepatic failure.¹⁷ For example, in a recent report¹⁰ 37 per cent of the patients had received abdominal paracenteses before entering the hospital. It is difficult to compare this group with the present series, in which 74 per cent previously received paracenteses. The type of cirrhosis also may be an important consideration, for there is evidence that postnecrotic cirrhosis is less responsive to dietary treatment than Laennec's cirrhosis. When postnecrotic cirrhosis is present, less favorable results from dietary treatment may be anticipated. At present, the clinical differentiation of these two forms of cirrhosis is often impossible.

Experimental studies on animals have suggested that meat or meat juice may contain noxious substances that are not readily detoxified by the liver. However, in the patients under observation there was no apparent intolerance to animal proteins. On the basis of other studies, restriction of dietary fat has been advocated. The rationale stems from experiments which show that diets rich in fat, in conjunction with a low content of protein, predispose to hepatic injury. It may be

intestinal hemorrhage. Death from esophageal varices is in a sense accidental rather than an expression of impaired function of the liver. This appears to have been the case in 6 patients whose health was good in other respects. In the remaining cases of esophageal hemorrhage there were obvious signs of hepatic failure, the hemorrhage serving as a *coup de grâce*.

The chief causes of death for the entire series are listed in table 3.

POSTNECROTIC CIRRHOSIS (COARSELY NODULAR CIRRHOSIS)

On the basis of pathologic observations there appears to be good evidence for differentiating postnecrotic cirrhosis from Laennec's cirrhosis. In 3 well documented cases of the present series acute infectious hepatitis preceded hepatic failure by twelve, ten and five years, respectively. At autopsy the gross and microscopic observations were typical of postnecrotic cirrhosis. The fact that these cases remained "true to type" despite the long time intervals suggests that postnecrotic cirrhosis is an entity and not a stage in the evolution of Laennec's cirrhosis.

In the present series the disease in 15 cases was classified as postnecrotic cirrhosis. In 8 instances the diagnosis was based on presumptive clinical evidence, and in 7 instances the diagnosis was confirmed at autopsy. There were 8 men and 7 women. Seven of these patients were under 40 years of age, the average

pointed out that when adequate protein is fed, no such deleterious effects have been produced. Severe restriction of fat decreases the palatability of the diet and thus tends to reduce the caloric intake. In the present regimen a diet containing 170 Gm. of fat did not cause steatorrhea. Moreover, biopsy specimens of the liver obtained in the course of treatment did not reveal fatty changes in the liver. A recent report by Labby and Hoagland¹⁶ on the treatment of acute hepatitis also concluded that severe restriction of fat is not justified by clinical evidence.

In recent years a number of reports have suggested that the administration of choline or methionine may produce effects apart from that provided by diet. For reasons stated, it is not easy to evaluate these reports. It is far more difficult to establish controls and to determine the role of a specific dietary factor in studies of human beings than in experiments with animals. Our own limited experience does not suggest that choline and methionine exert a specific effect in the late stage of hepatic failure. It would seem that their field of greatest usefulness might be in the precirrhotic fatty stage of the disease, since they are lipotropic agents. There appears to be no danger in administering these substances, but there may be harm in stressing their importance to the extent that other factors are neglected. Although observations on laboratory animals have established that choline and methionine protect against experimental cirrhosis produced by diets low in protein, the evidence for their curative effect has been less conclusive. Certainly, it has not been shown that these substances alone are adequate for repair or regeneration of the cirrhotic liver. It is possible that several factors may facilitate repair of the liver and restoration of function.

Since concentrated albumin solution was administered to only 3 patients, the present study does not help define its usefulness. In 3 of 10 patients given liver extract intravenously, added therapeutic benefit may have been observed.

The implications of the present study are essentially those stated in an earlier report.²

The present data give no indication as to whether vitamin B concentrates, protein or some unknown substances are specifically effective in the treatment of cirrhosis. It is possible that, by maintaining patients in optimal nutrition and rest, the liver recovers "spontaneously." In other words, the present regimen may allow the patient to survive long enough for natural reparative processes to take effect. It is also possible that the present regimen provides a specific agent for recovery of the diseased liver. The fact that only a limited number of patients survive despite therapy does not rule out the latter possibility. When the diagnosis of cirrhosis of the liver can be made in the incipient stages, the mortality rate should become much reduced, for, unlike most other vital organs of the body, the liver has the capacity to regenerate. In this capacity lies the hope for an effective therapy.

SUMMARY AND CONCLUSIONS

The present report describes results obtained in the treatment of 124 patients with cirrhosis of the liver in failure. The therapeutic regimen included a nutritious diet, rich in protein and supplemented with vitamin B concentrates, bed rest, abstinence from alcohol, diuretics and supportive care.

Evidence for clinical improvement was observed in 61 cases. Their improvement fulfilled three criteria: (1) disappearance of ascites, jaundice and edema. (2) gain in weight and strength and (3) improvement in

tests of hepatic function. It generally required several months before substantial changes took place.

The duration of life after the onset of ascites was significantly greater in the present series (115 cases) than in a control series (230 cases). At the end of one year, 65 per cent of the treated patients were alive and 39 per cent of the controls; at the end of two years, 50 per cent of the treated patients and 21 per cent of the controls were alive, and at the end of five years 30 per cent of the treated patients and 7 per cent of the controls were alive.

Therapeutic trial was made of choline, methionine, concentrated human serum albumin and liver extract administered intravenously in a small group of patients who had been refractory to treatment. The experience in this group is too limited to be of significance.

It is concluded that Laennec's cirrhosis is not, of necessity, a progressive disease. With early diagnosis and early institution of treatment the prognosis should become more favorable.

HAZARDS OF THIOCYANATE THERAPY IN HYPERTENSION

DONALD L. KESSLER, M.D.
and
LAURENCE E. HINES, M.D.
Chicago

The evaluation of any therapeutic agent in the treatment of essential hypertension is exceedingly difficult, because there is a tendency for exacerbations and remissions to occur spontaneously. Much has been written about the cures, but little about failure. In recent years thiocyanates have been used enthusiastically. This is an example of a custom, not too rare, of reviving and injecting new enthusiasm into ancient discarded treatments. The story of the thiocyanates began in 1903 with Pauli, who suggested the use of potassium thiocyanate as a hypotensive agent. The drug was little used until Westphal in 1924 presented a favorable report. In a few years the thiocyanates again fell into disrepute because of the frequency of toxic manifestations, until Barker in 1936 controlled the toxic effects by checking the level of thiocyanates in the blood. Since then numerous observers have concluded that the continuous administration of the drug under adequate control produces a persistent lowering of the blood pressure in normal persons, in about three fifths of those who have glomerular nephritis and in about one third of those who have essential hypertension.¹

PHARMACOLOGIC ASPECTS

The thiocyanate ion is similar in effect to the iodide ion. When ingested a high percentage of the drug is distributed to the extracellular fluid and thus influences the aggregation of colloids in a manner similar to the iodides and the other haloids. It is excreted chiefly by the kidneys, but more slowly and less completely than the haloids.

Potassium thiocyanate has a sedative action in moderate dosage.² In lethal doses it is irritating to the anterior horn cells.³ Symptoms varying from mild

drowsiness to toxic psychosis have been reported. It has a paralytic action on muscle similar to that produced by curare.^{2a} Certain effects on the blood have been emphasized, particularly the reduction in the erythrocyte count, hemoglobin, hematocrit, serum proteins and cholesterol and elevation of the sedimentation rate.⁴ It produces smooth muscle relaxation.⁵ The drug does not increase peripheral blood flow, nor does it produce peripheral dilation.⁶ Cardiac depression, increased cardiac output and decrease in the size of the heart have been reported.⁷

Potassium thiocyanate increases the flow from mucous glands.⁵ Goiter frequently follows its administration.⁴ Diuresis is often produced.⁸ Depression of metabolism of the liver occurs.^{6b}

In human beings the number and severity of toxic symptoms are roughly proportional to the serum thiocyanate level. With serum levels less than 12 mg. per hundred cubic centimeters, weakness, fatigue, depression, exhaustion, somnolence, apprehension, nervousness, nightmares, tinnitus, pruritus, dry skin, various dermatitides, nausea, vomiting, abdominal pain, diarrhea, anemia and goiter are commonly noted. With blood levels higher than 12 mg. per hundred cubic centimeters, these symptoms and other more serious effects, such as fever, loss of hair, angina, purpura, gastric hemorrhage, vertigo, twitching, convulsions, disorientation, confusion, slurred speech, hallucinations, unsteady gait, motor aphasia, paralysis of the lower extremities, exfoliative dermatitis, collapse, coma and death, have occurred.

The mechanism producing the hypotensive effect is not known. It parallels the serum thiocyanate level. The sedative action of the thiocyanate ion is insufficient to account for the fall in blood pressure, for the more efficient soporifics, such as the bromides, chloral and the barbiturates, fail to produce comparable results. The changes in blood composition, with the exception of the decreased cholesterol, are reproduced almost identically by repeated venesections.

Barker and Davis⁹ have demonstrated that a reduction in blood pressure is produced by thiocyanate administration in hypertensive Goldblatt dogs. This is evidence that its effect is not that of relieving arteriolar spasm in the kidney, for the Goldblatt clamp mechanically prevents an increase of blood flow to that organ. There is no evidence that the thiocyanates act as deactivators for the pressor substances described by Page. There is no evidence at present which suggests that its hypotensive action is due to breakdown products of the drug in vivo. It has been suggested that the hypotensive effect is a response to the ingestion of a protoplasmic poison.

REPORT OF CASES

The following cases, including 1 in which there was fatal poisoning, are reported to illustrate toxic effects of thiocyanate therapy.

CASE 1.—Mrs. H. L., a 48 year old white woman, first entered St. Joseph Hospital in December 1945, complaining of nervousness, malaise, intermittent "spells of numbness" involving the entire body and high blood pressure of many years' duration. Physical examination and laboratory, roentgenologic and electrocardiographic studies at that time failed to reveal any significant evidence of cardiac or renal disease. The mean systolic blood pressure during that period of hospitalization was 250 and the mean diastolic pressure 150 mm. of mercury.

This patient received thiocyanates for three months. The serum thiocyanate level was maintained between 8 and 15 mg. per hundred cubic centimeters. After attempts to produce a significant fall in blood pressure failed and severe occipital headaches developed, sympathectomy was advised. In April 1946, a thoracolumbar sympathectomy was performed.

The patient again received thiocyanates, until Feb. 7, 1947, when she reentered St. Joseph Hospital, complaining of extreme tiredness, dizziness, weakness and vomiting of two days' duration. The essential observations were confusion, disorientation, inability to give a coherent chronologic history and hesitant speech. The retinal vessels showed moderate nicking and a decrease in the auriculoventricular ratio. The systolic blood pressure was 260 and the diastolic pressure 114 mm. of mercury. Neurologic examination failed to demonstrate any abnormal changes other than the confusion previously noted. There was mild microcytic hypochromic anemia and a trace of albumin in the urine. The nonprotein nitrogen was 27 and the serum thiocyanate level 8.8 mg. per hundred cubic centimeters.

No treatment other than bed rest was given, and for ten days the patient's condition remained unchanged. Her blood pressure during that period varied from 230 systolic and 205 diastolic to 112 systolic and 110 diastolic (mm. of mercury). Although the thiocyanate therapy was stopped on admission, the serum thiocyanate level ten days later was 8 mg. per hundred cubic centimeters. After eighteen hospital days the mental symptoms had completely subsided and the patient's blood pressure was 235 systolic and 110 diastolic mm. of mercury. At this time the serum thiocyanate level was 5.5 mg. per hundred cubic centimeters.

CASE 2.—Mrs. C. D., a 64 year old white woman, entered St. Joseph Hospital on March 3, 1947, complaining of weakness, palpitation, slurred speech, inability to concentrate, mild disorientation and soreness of the mouth, tongue and lips of seven days' duration. Nine years previously, following a routine physical examination, she was told that she had high blood pressure. A 1,000 cc. venesection was done, and she was given 0.03 Gm. of phenobarbital and 0.3 Gm. of theobromine calcium salicylate three times daily. She had no symptoms for nine years. In February 1947, persistent occipital headaches developed, and she was given potassium thiocyanate, 0.3 Gm. three times daily. A serum thiocyanate level two weeks later was 8 mg. per hundred cubic centimeters. One week later the symptoms previously noted developed.

The patient had an unsteady gait and slurred speech and was mildly disoriented. She was irritable and apprehensive. The retinal vessels showed mild silvering and nicking. The systolic blood pressure was 190 and the diastolic pressure was 85 mm. of mercury. The apical impulse was in the fifth interspace, 13 cm. from the midsternal line. There was a soft mitral systolic murmur. The lungs, abdomen, back and extremities were normal. The results of laboratory examinations on admission were as follows: the nonprotein nitrogen was 22, blood sugar 96, vitamin C level 1 and serum thiocyanate level 22 mg. per hundred cubic centimeters. The sedimentation rate was 21 mm. per hour; phenolsulfonphthalein excretion was 67 per cent in one hour. Urinalysis showed a trace of albumin and a few leukocytes and hyaline casts. The electrocardiogram showed only minor changes.

The potassium thiocyanate therapy was stopped and the patient given bed rest. Eight days later the serum thiocyanate

level was 10 mg. per hundred cubic centimeters, and she had no complaints. Her blood pressure during this period varied from 188 systolic and 140 diastolic to 96 systolic and 70 diastolic (mm. of mercury). The patient was discharged fourteen days after admission, with a serum thiocyanate level of 8 mg. per hundred cubic centimeters.

CASE 3.—R. J., a 52 year old white man, entered St. Joseph Hospital Nov. 26, 1946. One month earlier hemiplegia had developed, and the patient was hospitalized in Indianapolis. A letter from his physician included the following data: the patient was pale and sweating; there was a partial paralysis of the left side, with hyperactive deep tendon reflexes; his systolic blood pressure was 260 and diastolic pressure 150 mm. of mercury. He was given 0.3 Gm. of phenobarbital four times daily, 20 cc. of 10 per cent magnesium sulfate intravenously daily, theobromine calcium salicylate, 0.3 Gm. three times daily, and potassium thiocyanate, 0.26 Gm. three times daily. In twenty days his systolic blood pressure had dropped to 170 and diastolic pressure to 92 mm. of mercury. The thiocyanate level increased from 2.8 mg. per hundred cubic centimeters on the second hospital day to 20.8 mg. on the twentieth hospital day.

Section of liver, showing central necrosis and peribulbar hepatitis (case 3).

When first observed in Chicago, on November 21, five days after leaving Indianapolis, he was drowsy, sweated profusely, salivated excessively and showed signs of auditory and visual hallucinations. He was acutely ill when admitted to St. Joseph Hospital November 26. The skin was icteric. There was generalized weeping crusted exfoliative dermatitis. The lips were dry and scaling. There were many small shotty cervical lymph nodes. The thyroid gland was diffusely enlarged. The systolic blood pressure was 130 and diastolic pressure 90 mm. of mercury. The heart was slightly enlarged to the left. The rhythm was regular. There were no murmurs. The lungs were clear. The abdomen was normal. The deep tendon reflexes were more active on the left than on the right. There were no pathologic reflexes. The left arm was paralyzed.

The laboratory reports on admission were as follows: red blood cells, 3,900,000, white blood cells 7,750, hemoglobin 12 Gm., sedimentation rate 25 mm. per hour, icterus index 60 units, nonprotein nitrogen 60, and serum thiocyanate level 25.3 mg. per hundred cubic centimeters. Culture from the cutaneous rash showed nonhemolytic *Staphylococcus albus*. The electrocardiogram showed a rate of 90 per minute, with the PR interval 0.14 seconds, QRS complexes 0.06 seconds, sinus rhythm, slurred QRS complexes in all limb leads and a low T wave in leads 1 and 3. The patient received fluids, penicillin, vitamins and sedation. On November 27 the temperature was 100.6 F. and then rose daily to 101 F. Soon signs of pneumonia developed in both lungs, and the patient died seven days after admission.

Necropsy showed generalized icterus, generalized exfoliative dermatitis, extensive necrosis of the liver, arteriolar nephrosclerosis, cerebral edema and an area of softening in the internal capsule.

The skin was thickened, rough, red and covered with flaky white scales, more apparent over the extensor surfaces of the extremities. There were scattered areas where the lesions were moist and weeping. Microscopic examination showed a focal subepithelial inflammatory cell infiltration, consisting of lymphocytes, plasma cells, leukocytes and eosinophils. The surface epithelium was absent in most areas.

The liver weighed 1,890 Gm. The capsule was smooth. On cut section the tissue was light yellow, mottled with tiny brown spots. Microscopic examination showed more than one half of each lobule to have decided lymphocytic infiltration around the portal radicles and decided necrosis of the parenchyma around the central veins.

The heart weighed 480 Gm. The left ventricle was hypertrophied. The coronary arteries were tortuous and contained many atheromatous plaques. The lungs showed vascular engorgement and focal areas of suppuration. The gallbladder, spleen, pancreas and adrenals were grossly normal. The kidneys showed extensive cloudy swelling and degeneration of the tubular epithelium. There was fibrosis of many glomerular tufts. The brain was edematous. There was an area of softening 2 by 1.5 by 0.5 cm. in the right internal capsule. A tissue assay for thiocyanate revealed 6 mg. per hundred cubic centimeters in the myocardium, 7.5 mg. per hundred cubic centimeters in the kidneys and 3.6 mg. per hundred cubic centimeters in the brain.

SUMMARY

Three patients from a series receiving thiocyanate for essential hypertension sustained unusual toxic effects. The maintenance of serum thiocyanate levels between 8 and 12 mg. per hundred cubic centimeters is generally considered to be an optimum range for a good hypotensive effect without toxicity. In case 1 there were severe toxic symptoms originating from the central nervous system, while the serum thiocyanate level was only 8.8 mg. per hundred cubic centimeters. This patient had failed to show a fall in blood pressure while taking thiocyanates either before or after thoracolumbar sympathectomy. Another danger is shown in the second patient. She presented a sudden rise in serum level from 8 to 22 mg. per hundred cubic centimeters in less than one week with a dose of 0.9 Gm. daily. Here a dose which previously had maintained a stable level suddenly rose to a height which was capable of producing damage. In the third patient with extensive nephrosclerosis there was spectacular fatal poisoning; this patient had received large doses of the drug. Death was due to extensive central necrosis of the liver, periportal hepatitis and extreme dermal exfoliation. This case, of course, was improperly managed. Frequent studies of the blood should have been made because of the large doses of the drug and because he had severe renal disease. In such a patient there is a narrow margin of safety between a therapeutic and toxic dose.

These studies suggest that the results of thiocyanate therapy are not uniformly good. The drug may or may not produce a fall in blood pressure in the patient with essential hypertension. There appears to be a narrow margin of safety between therapeutic and toxic levels in some patients. Moderate toxic symptoms are common even when blood levels are within a zone recommended as safe. In the fatal case the liver sustained extensive damage from an excessive dose. Thus it is seen that the thiocyanates, used in the treatment of a disease the mechanism of which is not well understood, are capable of some harm; indeed, it is possible that the hypotensive action is an effect produced by ingestion of a protoplasmic poison.

104 South Michigan Avenue.

the hope of preventing, or at least delaying, recurrence. Daily injections for such a long period of time, pain and localized reactions were the chief reasons for this failure. Accordingly, we outlined the following routine to which we hoped to adhere in each case: six injections per week, for a period of at least three months (and if possible for a total of ninety injections), to be followed by daily administration of enterogastrone tablets for an additional twelve months. Since it was reported that enterogastrone given orally, as well as parenterally, offers protection and resistance against the development of Mamm-Williamson ulcers,⁷ it was thought advisable to supplement the parenteral treatment with oral treatment.

3. A number of our patients were unable to visit the office for daily injections over a prolonged period of time. Accordingly, arrangements were made with a nurse or a member of the family to administer the drug. Twenty-one patients thus received enterogastrone injections in their homes. Of this number, in spite of the fact that all were instructed to receive injections daily (exclusive of Sundays), only 11 followed this routine. Seven of the remaining patients were treated five days per week and 3 only four days per week. Of the 21 patients who were treated in our office, all but 5 received daily injections exclusive of Sundays.

The parenteral enterogastrone extract was supplied in the form of enterogastrone hydrochloride, 200 mg. in weight, preserved as a "cake" in an ampule which represents a single "dose." This was prepared by The Upjohn Company in accordance with directions supplied by Dr. Ivy. The "cake" was dissolved either in 5 cc. of double distilled water or 5 cc. of isotonic sodium chloride solution and injected intramuscularly either in the buttocks or arms, as preferred by the patients. The enterogastrone tablets were prepared by Abbott Laboratories and were supplied in 0.5 Gm. tablets, and 14 tablets were administered daily in divided doses (7 Gm. per day). The patients receiving parenteral therapy at the office were seen by one of us daily; those who were treated in their homes were interviewed once a week. During the period of oral therapy the patients reported at regular intervals for interview and examination.

IMMEDIATE RESULTS

Table 1 summarizes the results obtained among the patients treated with six injections per week, five injections per week and four injections per week, as well as the results obtained among the patients treated in the

TABLE 1.—Parenteral Enterogastrone Therapy;

office (by one of us) and the patients treated in their homes (by a nurse or a member of the family). It will be noted that:

1. Of the 27 patients who were treated parenterally six times a week (average: eighty-one injections), only 14, or 52 per cent, became symptom free and 3, or 11 per cent, were moderately improved. Ten of the patients (37 per cent) failed to obtain any symptomatic improvement.

2. Of the 10 patients who were treated five times a week (average: eighty injections) 8 became symptom free; of the 5 patients who received four injections weekly (average: sixty-two injections) only 1 was improved.

3. In the group as a whole, of the 42 patients treated parenterally only 23, or 55 per cent, obtained symptomatic relief during the three month period of enterogastrone therapy.

TABLE 2.—Relapses Within One Year from Institution of Enterogastrone Therapy

Number of patients who became symptom free during parenteral therapy.....	23
(1) Number of patients with recurrence during the first three months of treatment and while still receiving injections	7 (30.4%)
(2) Number of patients who had recurrence three to six months after the start of enterogastrone therapy and while still receiving enterogastrone orally	3 (13.0%)
(3) Number of patients who had recurrence six to twelve months after the start of enterogastrone therapy	6 (26.1%)
(4) Total relapses within one year from the start of enterogastrone therapy	16 (70.0%)

4. Hemorrhage developed in 3 patients while they were regularly receiving injections with enterogastrone (after ninety, ninety-eight and one hundred and fifteen injections). They were hospitalized and treated with the usual conservative regimen without further parenteral therapy.

5. In 2 patients the pain became intractable during treatment (after forty-five and sixty-nine injections), and they were subjected to subtotal gastric resection.

6. Of the 5 patients with hemorrhage and intractable pain, 4 received six injections weekly and 1 was treated five times weekly.

7. Twenty-one patients were treated by one of us at the office, and a similar number of patients were given injections by a nurse or a member of the family in their homes. It will be noted that of the patients treated in the office (and given injections by a physician) only 24 per cent of the patients failed to experience any improvement in symptoms, while of the patients given injections in their homes (by a nurse or a member of the family) 48 per cent failed to show any symptomatic improvement during the three month period of enterogastrone therapy (average: ninety-one injections).

It is important to stress that during the first three months of treatment, our therapeutic regimen was in no way different from that followed by Greengard and his associates.¹

RELAPSES WITHIN ONE YEAR FROM BEGINNING OF ENTEROGASTRONE THERAPY

Continuation of enterogastrone therapy (after the three month period) in the 19 patients who failed to obtain symptom-free intervals did not seem warranted even had the patients agreed to further trial. Accordingly, our interest was focused on the 23 patients who had symptom-free intervals during the parenteral administration of this product. These 23 patients were asked to continue with the liberal modified diet for ulcer and, in addition, to take 14 enterogastrone tablets daily. In this respect, our series differed from that of Greengard and his co-workers¹ who continued injections for three to nine months longer. A summary of

the results under our regimen in these 23 patients is presented in table 2. It will be noted that:

1. Seven of the 23 patients, or 30 per cent, had relapses during the first three months of treatment and while still receiving injections. (Three of these patients were given injections six times weekly and 4 were

† Mostly patients with chronic ulcers, analogous to groups 4 through 9.

given injections five times weekly.) One patient had a recurrence within two months after parenteral therapy was instituted (six injections a week; office treatment) and continued until ninety injections had been given, after which he took tablets orally for an additional two months. He refused further treatment after a second recurrence. The remaining six patients had attacks within three months after injections had been started (3 had six injections per week, and 3 had five injections per week). Two of these 6 patients continued with treatment until one hundred and fifteen and ninety-eight injections, respectively, had been given; they then took tablets for one and two months, respectively, but failed to return for additional tablets or further observation.

2. There was recurrence in 3 patients within three to six months after enterogastrone therapy had been instituted and 6 patients within six to twelve months. All of these patients received six injections a week (an average total of seventy-one injections) and continued with oral administration of enterogastrone from one to thirteen months, but had recurrence during treatment.

3. In the 23 symptom-free patients as a group, 16 (70 per cent) had recurrences within one year after the start of enterogastrone therapy. Each of 12 of the patients had six injections a week, and 9 had at least ninety injections. Only 7 patients (30 per cent) were still symptom free one year after treatment was begun. Three of these 7 patients each received six injections a week (average: eighty injections); 3 received five injections a week (average: ninety-seven injections), and 1 received four injections a week, a total of only thirty-eight injections.

COMPARATIVE RESULTS

Previously, one of us (D. J. S.) employed other products parenterally for patients with chronic duodenal ulcer, i. e., vaccine, histidine, emetine, "anthe-

lone" and distilled water injections. In addition three other series of patients with duodenal ulcers, treated with the usual diet-alkali-antispasmodic regimens (ambulatory and hospital bed rest); were analyzed for the effect of these regimens on symptoms and relapses. Detailed data on the results of treatment in these eight different series of patients have been reported.⁸ It must be stated that the patients treated with enterogastrone (the present and ninth series) were treated more frequently and over a much longer period of time.

Tables 3 and 4 present the comparative results. It will be noted that enterogastrone therapy does not present superior results over the other regimens, either in its immediate effect on symptoms or in its remote effect on "immunizing" patients against recurrence. It will also be noted that the lowest percentage of relapses within one year occurred among those patients who followed a dietary regimen.

"IMMUNITY" AGAINST RECURRENT SYMPTOMS

It has been definitely demonstrated by Ivy and his associates that in Mann-Williamson dogs enterogastrone therapy prevents, or at least delays, recurrent ulceration. This so-called "immunity" against recurrent ulceration continues even after enterogastrone therapy is discontinued, provided, however, that enterogastrone is administered for a period of at least three months.

His co-workers¹ have applied this to man. They reported that therapeutic trial on 58 patients (and 43 Mann-Williamson dogs) "has demonstrated the probability that the material [enterogastrone] is effective in preventing recurrence during the period of its administration, and for a length of time thereafter of a duration as yet undetermined."

Our clinical results are not in agreement with this opinion. Of 33 patients who have had a full three month course of parenteral therapy (an average total of eighty-nine injections), 13 patients continued to

have symptoms at the end of the three month period; 2 were moderately improved, and 18 were symptom free. Of the 18 patients who were symptom free at the end of the three month therapeutic regimen, 13 had

8. Sandweiss, D. J., and Meyers, S. G.: Treatment of Peptic Ulcer with Bacterial Vaccine (Foreign Proteins), *Am. J. Digest. Dis. & Nutrition* 1: 338-341 (July) 1934. Sandweiss, D. J.: Treatment of Peptic Ulcer with Histidine Monohydrochloride, *M. A.* 100: 1452-1459 (April 25) 1936; Dietetic, Parenteral and Surgical Treatment in 700-705 (Feb. 25) 1937. Sandweiss, D. J., and Sullivan, M. H. F.; Saltzstein, H. C., and Farberman, A. A.: The Effect of Urine Extracts on Peptic Ulcer, *Am. J. Digest. Dis.* 8: 371-382 (Oct.) 1941.

recurrence of symptoms within one year (2 of these had hemorrhages during the year) and in 1 a perforation developed fourteen months after the institution of treatment. Only 4th of the 33 patients (12 per cent) were still symptom free approximately one year after completing the three month course of parenteral therapy.

It should be stressed that 10 of the 14 patients who had subsequent recurrences had had the added advantage of enterogastrone given orally for many months after parenteral treatment with enterogastrone was discontinued and that the symptoms recurred while these patients were still receiving enterogastrone orally.

It should also be noted that, since three months of treatment have been recommended to establish "immunity," this analysis includes only the results obtained after three or more months of treatment. In these 33 patients we have accordingly disregarded symptoms or recurrences during the first three months.

STUDIES OF SECRETION

Studies of gastric secretion were made on 9 patients before and after enterogastrone therapy, using 300 cc. of 3 per cent alcohol as a test meal. In 4 patients there was a moderate reduction in free hydrochloric acid concentration; in 3 patients there was no change, and in 2 there was a moderate elevation of free hydrochloric acid concentration.

Pollard and his associates⁹ failed to note any change in the fasting volume of gastric secretion or output of hydrochloric acid following daily oral or parenteral administration of enterogastrone for a period up to eleven months. They also failed to note any change after single intramuscular injections of 200 to 800 mg. of enterogastrone.

Kirsner's studies¹⁰ on patients with peptic ulcer are of interest. In a personal communication to us he stated: (1) Nocturnal and twenty-four hour gastric secretion "may decrease" in human beings after the intramuscular injection of 1,000 to 3,000 mg. of an enterogastrone concentrate. The inhibition is variable in degree and not consistently related to the dosage. (2) The secretion of acid "may increase" during the administration of enterogastrone and, also, twenty-four and forty-eight hours later. The significance of these results will be commented on later.

ROENTGENOLOGIC STUDIES

We did not study our patients roentgenologically after enterogastrone therapy. However, of 17 patients so studied by Pollard and his co-workers,⁹ the roentgenographic appearance "was unchanged in 8 cases, improved in 6 and definitely worse in 3."

SIDE EFFECTS

Our first 2 patients experienced generalized urticaria after each of the first two injections. We subsequently prevented urticaria by injecting, at first, smaller amounts of enterogastrone in patients observed to be sensitive to preliminary intradermal tests. A number of the patients presented redness, soreness and induration, which at times extended over an area of 5 to

10 inches (about 13 to 25 cm.) in diameter. These rarely lasted longer than forty-eight to seventy-two hours. The injections were painful to most of our patients, even to those who did not have local reactions. Several complained that they could not work or drive a car for two to three hours after each treatment. A few patients wondered about residual slightly tender "bumps." These were small round indurated areas, apparently deep in the muscles into which the injections had been given, which as a rule completely disappeared within a week or two after each treatment. None of our patients experienced generalized reactions, such as chills, fever or influenza-like symptoms. These side effects were in no way related to clinical end results.

COMMENT

The experimental data reported by Hands and his co-workers⁴ and Ivy and his associates¹¹ indicate that treatment with enterogastrone extracts have a prophylactic, curative and "immunizing" effect on Mann-Williamson ulcers. However, in the light of our disappointing clinical experience, one might well ask whether encouraging experimental results on Mann-Williamson dogs are always applicable to ulcers in human beings.

The Mann-Williamson ulcers, according to Mann, Ivy and others (as well as in our own experience), have both the gross and microscopic characteristics of those seen in peptic ulcer in human beings. For this reason, physiologists commonly use Mann-Williamson dogs to test the therapeutic efficacy of various regimens for ulcers. However, there are definite fundamental differences between the Mann-Williamson ulcers and those seen in human beings. An ulcer hardly ever develops in the dog spontaneously. Also, in the Mann-Williamson dog the ulcer develops at the jejunum; this ulcer develops only following a surgical procedure, i. e., a gastrojejunostomy plus surgical duodenal drainage.¹² By this surgical procedure, the jejunum is deprived of all pancreatic enzyme (trypsinogen, amylase and lipase), bile (bile salts, acid and pigments) and the duodenal secretions. In addition, there is a disturbance in the acid-alkali relationship in the jejunum of the Mann-Williamson dog as compared with the normal jejunum. In short, there is a total disturbance of all biochemical processes of digestion. As a result, as a rule, nutritional disturbances develop in the dog. The untreated animal invariably dies within five months following this operation, and in our experience approximately 75 per cent of the animals die of peritonitis following perforation of the ulcer.

We thus question whether duodenal ulcer in human beings is similar to the ulcer observed in Mann-Williamson dogs. Even the jejunal ulcer following a gastroenterostomy is not analogous to the Mann-Williamson ulcer, for when gastroenterostomy is performed in a human being the duodenum, with its contents, is never "detoured" to the terminal aspect of the ileum.

It might be stressed that if any agent promotes healing and prevents recurrences of Mann-Williamson ulcers, the same agent could be expected to produce similar results in patients in whom the processes of digestion and nutrition are not so much distorted as in

8a. One of these 4 patients had a hemorrhage recently (August 1948), about fourteen months after the institution of enterogastrone therapy. He had two hundred injections (six per week) and continued with enterogastrone orally. The hemorrhage occurred while the patient was still taking enterogastrone.

11. Greengard, Atkinson, Grossman and Ivy.¹ Ivy.⁶

12. In the Mann-Williamson operation the pylorus is anastomosed to the jejunum 15 to 20 cm. beyond the ligament of Treitz, and the duodenum and its entire contents is "detoured" to the terminal aspect of the ileum about 25 cm. proximal to the cecum.

the Mann-Williamson dog. In this respect, Ivy and his associates, in conducting an experimental test with enterogastrone as a possible medicament for patients, have made a distinct contribution, especially in the light of their encouraging clinical data. It is possible that our conflicting clinical results might be explained by variations in potency between the different lots of enterogastrone extracts. If so, the present method of preparing enterogastrone and the present method of assaying the product for potency need immediate reevaluation if enterogastrone is to be used therapeutically on patients.

Enterogastrone connotes the hormone derived from intestinal mucosa which suppresses gastric secretion and acidity. However, it appears, from the recent reports by Ivy¹³ and Greengard and his associates,¹ that enterogastrone concentrates contain not only a gastric secretory depressant factor (an antiacid factor) but also one which increases the resistance of the mucosa to ulceration (an antiulcer factor), which they consider probably responsible for the beneficial effect on Mann-Williamson ulcers. Greengard and his co-workers¹ said:

Such an action [gastric secretory depressant] completely fails to account for the findings that the duration of protection far outlasts the course of injections. . . . Support of this view is lent by the apparent protective effect in the dog of a crude acid extract of the intestinal mucosa when given by mouth in adequate doses; the secretory-inhibitor effect of enterogastrone is not elicitable by its oral administration.

Ivy¹³ also explained the protection provided by enterogastrone as due to antiulcer activity rather than antiacid activity, i. e., to an increased resistance of the mucosa to ulceration similar to that provided by "anthelone." Yet, the enterogastrone presently available and employed clinically is assayed only for its gastric secretory depressant potency. If enterogastrone produces a beneficial effect on Mann-Williamson dogs by its antiulcer activity (rather than by its antiacid activity) and, furthermore, since enterogastrone is employed clinically because it produces increased resistance of the mucosa against ulceration (without inhibiting gastric secretion in the patients, as was shown previously and suggested by Greengard and his co-workers) the product should then be assayed for antiulcer activity instead of for antiacid activity. This, unfortunately, is impossible at present, because a reliable method of assaying antiulcer activity quantitatively is as yet not available. In other words, the content of the active antiulcer ("anthelone") principle in enterogastrone is unknown.

As previously stated, Kirsner¹⁰ observed that nocturnal and twenty-four hour gastric secretion "may decrease" after the intramuscular injection of 1,000 to 3,000 mg. of enterogastrone concentrate and that the secretion of acid "may increase" during the administration of "enterogastrone" and for twenty-four and forty-eight hours. . . . gastric secretory stimulants may be extracted from practically all tissues of the body¹⁵ as well as from the mucosa of other parts of the gastrointestinal tract (in addition to that of the pyloric mucosa),¹⁶ is it possible that the enterogastrone

concentrates have, in addition to a gastric secretory depressant, a gastric secretory stimulant? Furthermore, since enterogastrone has as yet not been isolated or prepared in pure form, can it be said that it is free not only from gastrin or histamine but also from cholecystokinin, secretin, enterocrinin, villikinin or duodenin (the other hormones or hormone-like substances present in the mucosa of the small bowel)? It appears to us that not only do we not know how much of the active principle we are injecting, but also, we do not know what other hormones or hormone-like substances we are administering when we inject enterogastrone concentrates.

On the basis of our experience, enterogastrone as commercially available at present is not to be considered for a routine therapeutic regimen in peptic ulcer. On the basis of Ivy's laboratory (animal) and clinical observations, further intensive studies on the physiologic and biochemical aspects of the small bowel concentrates are warranted in an effort to produce a better product.

SUMMARY

1. Enterogastrone was administered parenterally to 42 patients with proved chronic duodenal ulcers. The injections were given six, five or four times weekly during a period of three months (an average total of seventy-nine injections). The immediate clinical results were disappointing, since only 55 per cent of the patients had symptom-free intervals.

2. Twenty-three patients (55 per cent) had symptom-free intervals during the three month period of parenteral enterogastrone therapy. After the course of parenteral therapy was completed, the 23 patients were given enterogastrone tablets orally. Sixteen, or 70 per cent, of these patients presented symptoms of recurrent ulcer within one year after the institution of parenteral therapy.

3. Our clinical results with parenterally administered enterogastrone were compared with those previously obtained by one of us with the diet-alkali regimens and with other parenterally administered products (vaccine, histidine, emetine, "anthelone" and distilled water injections). Our comparative results indicate that: (a) treatment with enterogastrone failed to produce more satisfactory results than the other therapeutic regimens, either in its immediate effect on symptoms or in its remote effect on recurrent attacks within one year, and (b) the lowest percentage of relapses within one year occurred among those patients who followed the usual conservative dietary regimen.

4. Thirty-three of our patients had a full three month course of parenteral enterogastrone therapy (an average total of eighty-nine injections). Only 4 of the patients (12 per cent) were still symptom free fourteen months after completing the three month regimen. The remaining patients had either not had a symptom-free interval at the end of the three month period or had subsequent recurrences if they became symptom free. We are thus of the opinion that the enterogastrone we employed, when administered parenterally during a three month period (even if followed by oral administration of enterogastrone), does not produce "immunity" against recurrent ulcer.

5. For the present we are discontinuing the use of enterogastrone clinically. It is our opinion that: (a) enterogastrone as commercially available at present is not to be considered a routine therapeutic medica-

ment for peptic ulcer, and (b) further intensive studies on the physiologic and biochemical aspects of enterogastrone concentrates are essential to produce a better product.

ADDENDUM

We have recently treated two series of Mann-Williamson dogs with enterogastrone, using the hospital stock animal diet, and we compared the results with our control (untreated) series. Nine dogs which received daily injections of 200 mg. of enterogastrone parenterally (The Upjohn Company) showed no benefit.¹⁷ Fourteen dogs given 8 tablets (4 Gm.) of enterogastrone (Abbott Laboratories) daily by mouth showed some benefit.¹⁸ Perhaps the commercial preparations we used were not as potent as those previously used by Ivy and his associates.

TREATMENT OF SCABIES

Report of One Hundred Patients Treated with
Hexachlorocyclohexane in a Vanishing
Cream Base

A. BENSON CANNON, M.D.

and

MARVIN E. McRAE, M.D.

• New York

The introduction of a new drug for the treatment of a specific disease carries with it two main questions: Is it effective, and is it safe? The authors have tested a preparation of hexachlorocyclohexane in a vanishing cream base¹ in 100 consecutive cases of scabies. All the patients were cured with from one to three applications; no irritation or discomfort from the remedy were noted, and no sensitivity to the drug or the vehicle, either primary or secondary, was elicited. The preparation seems to us to be the most promising yet advanced for the cure of a disease which is widespread in all walks of life and constantly increasing in incidence.

Scabies constitutes one of the most frequently encountered diseases in dermatologic clinics, its incidence varying with climate, habits of personal hygiene and degree of intimate contact. Scabies affects all ages, all races and all strata of society, although it occurs less often and usually in a modified form in persons of clean habits. It is seen in office practice as well as in the clinic.

INCIDENCE

After World War I the prevalence of scabies increased steadily in Great Britain until, during World War II, it assumed epidemic proportions. In this country waves of increase have followed the Civil War, the period of mass immigration in the early 1900's and World War I. All indications are that another upsurge is now taking place.

In the United States Army, during the recent war, scabies was one of the principal causes of time lost through cutaneous disease. The incidence varied considerably with locale, but the over-all picture showed scabies to be fifth in frequency among disorders of the

skin. In private dermatologic practice, it is encountered in from 5 to 12 per cent of patients, according to several observers, and estimates for the population in general range as high as 18 per cent in some areas.

Unfortunately, recognition of scabies may not always be easy. Sometimes the diagnosis is so obvious that the patient presents himself with the statement that he has "the itch." Other cases can puzzle even the experienced specialist. Kaposi termed scabies "a chameleonic eruption which presents one of the most difficult diagnoses in dermatology." Regarding its widespread occurrence in the Army, Pillsbury, Sulzberger and Livingood² stated, "In connection with this disease, the deficiencies of the American medical educational system in respect to dermatology were strikingly apparent; most medical officers had no concept whatever of the chief diagnostic features of scabies, and little knowledge of its treatment." Therefore, a brief review of the diagnostic points may be in order.

The outstanding symptom is itching, almost always worse at night and when the patient is warm. The eruption is made up of papules, vesicles, linear scratch marks, pustules and "burrows," which are often excoriated by scratching. The distribution is rather characteristic; in typical cases lesions may be seen in the interdigital spaces of the hands, or flexor surfaces of the wrists, on the inner and outer aspects of the elbows, in the axillas, around the umbilicus, on the buttocks and inner aspects of the thighs, on the penis and scrotum in men and around the nipples in women. The eruption may become generalized, although the face and scalp usually remain free. In young children and in bedridden patients, the palms and soles and even the face are frequently affected.

In many cases the severe itching induces scratching, which frequently results in secondary infection. In some persons the eczematous or impetiginous manifestations may completely mask the original characteristics.

The pathognomonic lesion of scabies is the burrow, which is not often recognizable in adults, but may usually be located in children. It appears as a sinuous threadlike line, along the course of which may be seen one or more small vesicles. At the closed end of the burrow the acarid may sometimes be seen, particularly with the aid of a lens, as a grayish dot.

The distribution of burrows and acari does not correspond proportionately to that of the general eruption; the latter has been considered by some authorities to be due largely to sensitization,³ rather than to the actual presence of the mites. Heilesen⁴ stated: "Nobody has yet been able to give a satisfactory explanation of the pronounced tendency of the mites to gather on the sites of election. The investigations of the burrowing of the mite seem, however, to indicate that it prefers to bore into furrowed and folded skin regions, and has difficulty in burrowing where the skin is quite smooth."

DEMONSTRATION OF THE PARASITE

We wished to demonstrate the *Acarus scabiei* whenever possible in this series and were able to do so in the large majority of cases. Secondary infection or extensive excoriations occasionally made its recovery dif-

4. Heilesen, B.: Studies on *Acarus Scabiei* and Scabies, *Acta dermat.-venereol.* (Suppl. 14) 26: 1, 1946.

difficult or impossible. Regardless of the intensity of the eruption elsewhere, we have been most successful in obtaining specimens from the fingers and hands and have seldom found it necessary to look further. The frequent statement that 10 per cent of the mites will be found on the volar aspect of the wrists has not been borne out by our experience, as it was recovered from that location in only 2 instances.

The most satisfactory method in our hands has been with the use of a sharp Hagedorn needle. The point is inserted under the epidermis at the beginning of the burrow, which is laid open along its entire length. (This is usually painless if properly done, as the burrow is confined to the horny layer.) By teasing the blind end, the acarid may frequently be made to cling to the needle point and appears as a minute oval grayish speck. If this is placed on a glass slide and exposed to warmth, its activity will identify it to the naked eye. The microscope will be needed to reveal greater detail. If the acarid does not cling to the needle, the burrow is scraped lengthwise with the edge of the needle, and the resulting debris placed on a slide. A drop of

10 per cent sodium hydroxide clarifies the material, and when a cover slip is gently pressed into place, the inanimate mite, larva, ova or detritus will usually be clearly revealed under the microscope. When typical burrows cannot be observed, the vesicles may be similarly examined.

OLDER REMEDIES

Sulfur as a local application has long been known to be an effective scabicide and was used for many years before the acarid was first demonstrated by Bonomo and Cestoni in 1687 as causing the disease. Other preparations used have included peruvian balsam, tar,

Chemical structure of hexachlorocyclohexane.

betanaphthol and cresol. None of these, however, proved as effective, or stood the test of time, as did sulfur. All the older preparations were messy to apply, and many were malodorous and irritating. The treatments consisted of at least two steps: a bath with thorough scrubbing, followed by complete and vigorous application of the medicament to the entire cutaneous surface below the head, often as many as four applications being recommended. Dermatitis as a result of treatment has been a complication in as high as 25 per cent of cases.

In recent years, newer remedial agents, such as benzyl benzoate emulsions and the dichlorodiphenyltrichloroethane (DDT)-benzocaine-benzyl benzoate formula, have done much to remove these objections, but meticulous application has been necessary; burning on contact has been a frequent complaint, and there have still been many instances of irritation or sensitivity. Experience with benzyl benzoate emulsions in the Canadian Army led to the belief that it produced a sensitivity to wool,⁵

the pathogenesis of which is not as yet clear. It appears, therefore, that a new highly effective scabicide, virtually nontoxic and nonirritant, which is simple and pleasant to apply, may be gratefully received.

HEXACHLOROCYCLOHEXANE—A POTENT NEW INSECTICIDE

The chemical 1,2,3,4,5,6-hexachlorocyclohexane, with the chemical formula $C_6H_6Cl_6$, was first discovered to be a promising insecticide early in 1942 by Thomas (Slade⁶) in experiments to control the turnip flea beetle in England. It is sometimes incorrectly called benzene hexachloride; this is an entirely different organic compound, with the formula C_6Cl_6 . It has also been known as "666," but this is an undesirable term for it has also been used as a designation for a commercial antimalarial preparation.

The gamma isomer of 1,2,3,4,5,6-hexachlorocyclohexane has been observed to be the most effective and, in addition, is free from the odor of chlorine. It has been extensively tested as an insecticide by the Department of Agriculture, the Army Service Forces, the Kettering Institute and other agencies and has been demonstrated to be toxic to a large number of insects as a contact agent, a stomach poison or a fumigant,⁶ apparently acting on the central nervous system.

From the medical point of view, the drug is important in the control of chiggers, ticks, fleas, cockroaches, bedbugs and pediculi capitis, corporis and pubis, as well as of the *Acarus scabiei*. It was observed by Army authorities to be outstanding as a miticide, both by impregnation of uniforms and in field fumigation.⁷

EFFECT ON HUMAN BEINGS AND OTHER VERTEBRATE ANIMALS

Report no. 56 of the Medical Division, Chemical Warfare Service, dated Sept. 26, 1945,⁷ stated, in reference to the crude hexachlorocyclohexane: "To date, no cases of poisoning or toxic symptoms have been reported for man except headaches and irritation to the eyes, and if inhaled, to the nose and pharynx. . . . If large quantities are used, a face mask is suggested. . . . There are no reported cases of its having been handled sufficiently long to produce symptoms from absorption through the skin."

Tests of the gamma isomer in rabbits, guinea pigs, rats and mice, by the same authorities, indicated that this form of the drug is not readily absorbed through the skin or when taken by mouth. Dr. G. R. Cameron, Professor of Morbid Anatomy at University College Hospital Medical School in the University of London⁸ commented: "Unpublished work by Mr. F. Burgess and myself suggests that this compound is of relatively low toxicity when applied to the skin or administered orally in single doses. Fairly large doses given repeatedly are tolerated." He stated further: "We have not heard of any cases of intoxication in human beings."

Tests of the particular preparation used in the series which forms the basis for this report were previously

carried out in approximately 800 human subjects in various institutions, with no evidence of toxicity or of cumulative effect to date. In five hundred patch tests, with ten, fifteen or more repeat tests, no instances of sensitivity has occurred.⁹ Our report concerns its trial in 100 cases of scabies.

GAMMA ISOMER OF HEXACHLOROCYCLOHEXANE IN THE TREATMENT OF SCABIES

The preparation used is the gamma isomer of 1, 2, 3, 4, 5, 6-hexachlorocyclohexane 1 per cent in a vanishing cream base. It is white in color and has a faint, not unpleasant, odor.

An unselected series of patients with scabies were treated with this ointment. Thirteen of these were ward patients at City Hospital¹⁰; 10 were seen in office practice, and the remaining 77 were treated in the Vanderbilt Clinic. Men, women and children, of all ages and several races, were included in the group. The eruption ranged from mild to severe with extensive secondary infection. We included only cases with characteristic lesions, confirmed in most instances by demonstration of the itch mite.

PROCEDURE FOLLOWED

The following plan of treatment was used:

1. Physical inspection was carefully made, including examination for *Acarus scabiei*.
2. Without preliminary bathing, a thin film of the cream was rubbed into the entire cutaneous surface of infants and from the neck to the sole of the foot in adults. The average adult required 15 to 25 Gm. per treatment.
3. The patient was requested to refrain from bathing or washing the hands for twenty-four hours.
4. After the bath, he was directed to use fresh underwear and night clothes and to change the bed linen, seeing that all were well laundered before reuse.
5. The patient was reexamined at the end of one week. (This allows ample time for hatching of any ova that might still be viable).
6. Other members of the family were to be brought in at the earliest possible moment for examination, and treatment if required.

Our patients were observed weekly until the eruption had entirely disappeared. If there were signs of activity or any considerable pruritus, the treatment was repeated. It was realized that pruritus was not an accurate indication of uncontrolled infestation, as other factors could well be involved. A habit pattern might have become established or acarophobia have intervened. However, the rapidity with which itching was controlled in most cases led the authors to use this symptom as a retreatment index.

RESULTS

Results in the 100 cases are shown in the table. Complete relief from pruritus within twenty-four to forty-eight hours was reported by about half the patients, and many observed that itching ceased within two to three hours. Pronounced clinical improvement was seen in all cases after one application. Sixty-one, or nearly two thirds of those under observation, showed no signs of activity after a single treatment. Thirty-six were given two treatments, and 3 patients received three. All were cured. In no case could the acarus be demonstrated after the first application of the cream.

Irritation was not observed in a single instance. One young child made a questionable complaint of burning when the ointment was rubbed in, but otherwise there were no evidences of immediate or subsequent reaction.

Four patients when first seen had advanced eczematization as a result of constant scratching. These were treated with bland ointments for one to two weeks after completion of treatment for scabies.

Secondary infection, when present, was treated with antibacterial ointments. In some instances these were used before the scabicide cream was applied and in others after, and the results were equally satisfactory. In the few cases in which the hexachlorocyclohexane alone was used in the presence of mild secondary infection, control of the primary dermatosis and its accompanying itching and excoriation allowed prompt healing of the superimposed dermatitis without recourse to other measures. As in the uncomplicated cases, application of the cream caused no irritation or discomfort. All patients found the preparation cosmetically acceptable, nongreasy and nonstaining to the clothes and bed linen:

REPORT OF CASES

The following brief case histories illustrate the types of problems encountered. The first represents a recalcitrant case in which other remedies had failed:

CASE 1.—R. M., a white man aged 24, presented widespread persistent scabies eruption of over four months' duration. The patient was treated three weeks previously with 10 per cent sulfur ointment and one week later with 20 per cent benzyl benzoate emulsion, with little change in the rash or the symp-

Data in 100 Cases in Which Hexachlorocyclohexane Was Used for Scabies

Patients	Condition	No. of Treatments				Fail-ures	Reac-tions
		Total	One	Two	Three		
Adults	Uncomplicated	61	41	20	0	0	0
Adults	Secondarily Infected	5	1	4	0	0	0
Children	Uncomplicated	30	18	9	3	0	0
Children	Secondarily Infected	4	1	3	0	0	0
Total.....		100	61	36	3	0	0

tom complex. Following application of hexachlorocyclohexane cream, itching ceased within twenty-four hours, and when the patient was seen one week later all signs of activity had disappeared.

The following cases illustrate the fact that when one member of a family contracts scabies, all others must be examined; if affected, they should be treated simultaneously in order to avoid reinfection:

CASE 2.—A white family, E. H. aged 39, H. H. aged 41, R. H. aged 13, C. H. aged 11 and J. H. aged 7, contracted the disease. R. H. had returned from a boys' camp three months prior to examination with itching rash, and during the next two months all members of the family became similarly affected. *Acarus scabiei* was demonstrated. One week following treatment, all were free of symptoms and signs of activity except C. H., who still showed a few excoriated papules on the wrists, with slight itching. (*Acari* were not found, although carefully searched for). A second application of the cream caused complete disappearance of the eruption and itching.

The next case illustrates the fact that scabies should be suspected more often in private practice:

CASE 3.—Mrs. A. C., a woman aged 46, a private patient, was seen with an itching eruption of six months' duration. The patient stated that her husband had been under the care of a professor of medicine of a large eastern medical school for the past two years for a similar eruption, diagnosed as allergy. Many patch tests had been performed, elimination diets prescribed and local medicaments applied, with no relief. *Acarus scabiei* was demonstrated in the wife, and a single application of hexachlorocyclohexane cream caused disappearance of the rash and pruritus. The husband was then brought in and similarly cured.

9. Smith, L. W.: Personal communication to the authors.

10. Dr. Meyer Slatkin assisted in the treatment of patients at City Hospital.

The remaining case also illustrates the same point and, in addition, suggests that severe secondary dermatitis is no contraindication to the use of this new scabicide:

CASE 4.—L. B., a man aged 32, a private patient, complained of itching rash on the abdomen, more pronounced just below the ribs. (Two or three days later the wife was similarly affected.) His physician made a diagnosis of scabies and prescribed benzyl benzoate emulsion. Four days after he used this, blisters appeared on his hands, fingers and ears, with redness and swelling. The physician then prescribed starch baths, calamine lotion and pills. When first seen by one of us, the patient's hands and ears had improved somewhat, but severe generalized itching interfered with sleep. Typical lesions of scabies were present on the fingers, axillary folds, scrotum, abdomen and buttocks. There were also ecematized red scaly dime-sized to quarter-sized patches in those areas. Dried vesicles and bullae were seen. The diagnosis was scabies and dermatitis, and hexachlorocyclohexane cream was prescribed. On the following day there was great improvement in both the itching and the dermatitis.

TESTING OF PATIENTS FOR SENSITIVITY

All patients were requested to return from one to two months after cure for patch tests to determine the development of sensitivity. Thirty-four patients complied and were so tested, and in no instance was a positive reaction elicited.

One hundred and three untreated patients at City Hospital were given patch tests with the scabicide cream for primary irritation. Test sites were observed at the end of forty-eight and seventy-two hours. All reactions were negative.

Although no evidence of irritation was encountered in this series, it is realized that the possibility of sensitization to hexachlorocyclohexane or other ingredients of the cream must always exist. However, this toxicity potential is evidently low, and the development of hypersensitivity is rendered even more unlikely by the fact that the preparation is therapeutically effective on one or two applications in most cases and in our experience has never had to be used more than three times by any patient.

A small group of patients with pediculosis corporis and pubis were also treated with good results, but are not included in this report.

SUMMARY AND CONCLUSIONS

One hundred unselected patients with scabies were treated with a new preparation of the gamma isomer of hexachlorocyclohexane in a vanishing cream base, with 100 per cent cures.

The remedy was effective in cases in which other preparations had failed.

No cases of irritation or sensitivity occurred, either as primary or late manifestations.

No contraindications were elicited, even in the presence of severe secondary dermatitis.

The preparation was also successful in the treatment of pediculosis in the few cases in which it was tried.

Sodium Salicylate a Toxic Substance.—Sodium salicylate is widely used in the treatment of acute rheumatic fever and the more chronic forms of rheumatism. While there may be disagreement as to its precise value in the therapy of various rheumatic conditions, there is general agreement that it is a toxic substance giving rise to a variety of untoward and even alarming symptoms which may interfere with its administration. —Graham, J. D. P., M.D., and Parker, W. A., M.D., *The Quarterly Journal of Medicine*, April 1948.

TEMPERATURE COMPARED WITH RAT TEST FOR PREDICTION OF HUMAN OVULATION

A Study of Twenty-Seven Cases

EDMOND J. FARRIS, Ph.D.
Philadelphia

The fact that the body temperature varies during the menstrual cycle has been known for many years. The alteration in temperature which takes place at the time of ovulation has been employed as an aid in trying to overcome the infertility of certain couples. Tompkins,¹ in reference to the work of others, said:

All this literature may be summed up thus: A record of body temperatures taken daily under standard conditions shows a typical curve during the menstrual cycle. The temperature is relatively low during the first part of the month, drops to a minimum about the time that ovulation occurs and rises definitely thereafter to a relatively high level, which is maintained until the next menses, when the temperature drops abruptly.

Tompkins¹ stated:

If the temperature shows a rise of 2 or 3 fifths of a degree, and if this rise corresponds with a similar rise in the previous menstrual month and is not due to illness, then it can be assumed that ovulation is occurring and that intercourse is most likely to be fruitful. Intercourse more than once in twenty-four hours is probably unnecessary. (It is supposedly true that ovulation is indicated by the lowest temperature recorded. However, it is impossible to advise patients to have intercourse when the temperature is lowest, since it is impossible to determine in advance when the lowest point is reached. For this reason I have advised intercourse when the temperature shows a rapid rise.)

Greulich's² observations indicate that ovulation usually occurs after the temperature has passed its low point and has begun its rise. His observations were based on histologic studies of corpora lutea which were removed at operations performed after the observed rise in body temperature.

Buxton³ reported one hundred and twenty-seven temperature records. Three quarters of these were atypical. He concluded that it is practically impossible to predict the time of ovulation from knowledge of the temperature curve.

Since these observers and others have been unable to agree that ovulation occurs at a definite point in the temperature curve, it would seem doubtful that any correlation exists between time of ovulation and any definite point on the temperature curve.

In 1946 I⁴ reported a new method for detecting the time of human ovulation. Results obtained by Murphy and me⁵ indicated the practical value of this test in a study of 10 patients who conceived following the prediction of the day of ovulation. I shall report fifty additional conceptions timed by the rat test in a forthcoming paper.⁶

From the Wistar Institute of Anatomy and Biology.
This investigation was aided by a grant from the Samuel S. Fels Fund.

Suggestions made by Dr. Douglas P. Murphy have been incorporated in this paper.

The present communication deals with a series of women in whom ovulation was timed by the rat test. Each subject submitted a record of her basal body temperature taken during the months that the rat tests were being performed. Evidence is presented in order to illustrate the relative value of the two methods in the timing of ovulation. The day of ovulation was confirmed in each case by the occurrence of conception.

MATERIALS AND METHODS

Observations of 27 women were made. Basal body temperatures were taken rectally. The thermometer was placed in the rectum at the same hour each morning for a period of five minutes. This was done before the patient arose for the day. The temperature reading was recorded immediately on a graph.

The occurrence of ovulation was detected by the reaction of the ovary of the immature white rat to the urine of the patient.

The technic of the rat test is as follows: Two cubic centimeters of urine which the patient passes on arising in the morning are injected subcutaneously into 2 immature female white rats of the Wistar strain. Each animal is killed with illuminating gas at the end of two hours. The abdomen is opened. The two ovaries are drawn, one at a time, into the wound, and the color of each is compared with the graded

Fig. 1.—Basal body temperature records of 5 women who conceived before they experienced a rise in temperature. The graphs are arranged from above downward, from the shortest to the longest average length of menstrual cycle. The date of successful coitus is indicated, as determined by the rat ovulation test. The base line (abscissa) represents the days from the beginning of the menstrual cycle. The vertical line (ordinate) represents the rectal temperature. "O" inside the graph indicates a negative rat ovary reaction; "A" indicates a weak reaction; "+" represents a positive reaction. The latter indicates that the process of ovulation is under way, with ovulation impending, on the last cycle day of the "+" reaction. The points on the curve indicate intercourse or insemination; "O" on the temperature graph indicates intercourse or insemination, with an eight to ten hour interval. "C.D." marks the cycle day of conception; "A.I." indicates artificial insemination by homologous donor; "A.I.X." indicates artificial insemination by an anonymous donor. "Av. cycle days" indicates the average length of the menstrual cycles before conception occurred.

shades of red of the Munsell color system. In the presence of normal ovulation, the patient's urine induces hyperemia in the ovaries of the rat on four or five consecutive days.

The first month is utilized as a control. No attempt at conception is advised during this month. The control month tells whether ovulation occurs, when it takes place in relation to the duration of the cycle and whether the reaction is normal or abnormal. There is strong evidence to indicate that the egg is ready for fertilization on the last day of the reaction.

During the following month, intercourse is advised or artificial insemination is performed on the last day of the reaction, if the latter is normal.

Intercourse is interdicted during each testing period, since the act affects adversely the color reaction.

Twenty-three of the 27 women had their ovulation timed during the month that conception occurred. The remaining 4, who had been studied previously, were not available for timing during the months when they conceived. They had been advised, however, as to the probable date of ovulation. Sixteen of the women became pregnant by coitus and 9 by single inseminations

Fig. 2.—Basal body temperature records of 5 women who conceived before they experienced a rise in temperature. The graphs are arranged from above downward, from the shortest to the longest average length of menstrual cycle. The date of successful coitus is indicated as determined by the rat ovulation test. (Explanation of the symbols may be found in the legend for figure 1.)

—4 by anonymous donors and 5 by homologous donors. In 2 others insemination was with the husband's sperm, and they were advised to have coitus eight hours later.

The observations are presented according to the time that conception took place in relation to variation in basal body temperature: (1) before the rise, (2) at the drop, (3) during the rise and (4) after the rise.

RESULTS

The graphs in figures 1 to 6 are arranged from above downward, from the shortest to the longest average length of menstrual cycle.

Fig. 3.—Basal body temperature records of 4 women who conceived on the temperature drop. (Explanation of the symbols may be found in the legend for figure 1.)

The twenty-seven records presented in these figures reveal the fact that from two to fifteen days were required for the rising temperature to reach its highest point. The majority, or 59 per cent, of the temperature rises required four or more days. The temperature rise was abrupt in only 1 subject (K. D., fig. 1).

The cycles averaged twenty-four to thirty-four days in length. Conceptions occurred on cycle days 9 to

17, inclusive. The time elapsing between ovulation and menses (postovulatory interval) during the months before the one in which conception occurred averaged fourteen and seven-tenths days, with a range of from eleven to seventeen days.

Conception occurred before the rise in temperature in 10 cases (figs. 1 and 2). The actual day of ovulation as determined by the two hour rat test is indicated in the figures.

The case of P. W. (fig. 1) is typical. Her menstrual cycles averaged twenty-five days in length during the nine months before she conceived. Her temperature rose gradually from cycle days 10 to 25. The rat reaction indicated that her ovulation occurred on cycle day 11. Insemination on that day, with the sperm of an anonymous donor, resulted in pregnancy. The temperature change in this patient is difficult to interpret. It is assumed that the postovulatory interval of this patient during the month that she conceived would have been fourteen days in length.

Fig. 4.—Basal body temperature records of 5 women who conceived as their temperatures rose. The graphs are arranged from above downward, from the shortest to the longest average length of menstrual cycle. The date of successful coitus is indicated. (Explanation of the symbols may be found in the legend for figure 1.)

Figure 3 gives the temperature records of 4 women who conceived as their temperatures were dropping. The records of the first 2 subjects are complete. The record of the third woman is incomplete. The record of the fourth patient (E. B.) might be considered abnormal in view of the fact that her temperature exceeded 100 F. No explanation could be found for this unusually high temperature. The conception of this patient, which took place on cycle day 17, might be interpreted as having occurred either just before her temperature rose or while it was dropping.

Figures 4 and 5 contain the records of 10 women who conceived as their temperatures rose. The records of 5 of these women (C. B., H. R., W. M., D. T. and M. B.) are complete and conclusive. The records of the remaining 5 women are too incomplete to be conclusive, but suggest that the rise in temperature and ovulation were synchronous.

Figure 6 includes the records of 2 women who conceived after their temperatures had risen. The temperature of subject R. D. rose during cycle days 6 to 10, inclusive. Her conception occurred on cycle day 12. The temperature of subject H. K. rose during days 8

to 10. She conceived on cycle day 12, after insemination with the sperm of an anonymous donor.

The record of patient J. S. (case 27) is included in figure 6 to demonstrate a temperature shift which took place during the course of an unusually long cycle. The cycles of this woman averaged thirty-nine days in

Fig. 5.—Basal body temperature records of 5 women who conceived as their temperatures rose. The graphs are arranged from above downward, from the shortest to the longest average menstrual cycle length. The date of each subject's successful coitus is indicated. (Explanation of the symbols may be found in the legend for figure 1.)

length, with a range of from thirty-eight to forty-five days. Her temperature rose over a period of four days between cycle days 36 and 40. Conception occurred on cycle day 34, which was two days before her temperature rose.

The table summarizes the records of the 27 women, data for whom are detailed in the figures. It lists the cycle days during which the temperature rose from the low to the high point, the day of conception, the average length of the menstrual cycles before conception and the postovulatory interval.

The groups are arranged as follows: Cases 1 to 10 (from figures 1 and 2) are those in which conception

Fig. 6.—Basal body temperature records of 3 women who conceived. The first 2 women conceived after the rise in their temperatures. The ovulation (conception) date is indicated as determined by the rat ovulation test. The third subject (J. S.) conceived before her temperature rose. This record is listed separately because of the unusual length of the menstrual cycles, which ranged from thirty-eight to forty-five days and averaged thirty-nine days. (Explanation of the symbols may be found in the legend for figure 1.)

occurred before the temperature rise; cases 11 to 14 (fig. 3) are those in which conception occurred on the temperature drop; cases 15 to 24 (figs. 4 and 5) are those in which conception occurred during the tem-

perature rise, and cases 25 and 26 (fig. 6) are those in which conception occurred after the temperature rise.

In case 27 there were unusually long cycles, ranging from thirty-eight to forty-five days in length, with an average of thirty-nine days. The data in this case are listed separately.

COMMENT

Forty-one per cent of the twenty-seven conceptions occurred before there was any change in basal body temperature; 7 per cent took place after the rise. Fifteen per cent occurred as the temperature dropped; 37 per cent occurred during the rise. The latter two percentages are subject to question, as four of the temperature records were incomplete. If these records had been complete, they might have revealed a second drop in the temperature.

ing from patient to patient. From this study, therefore, it is concluded that the changes which may occur in the basal body temperature do not offer an efficient means for predicting the day of ovulation.

SUMMARY AND CONCLUSIONS

In 27 patients who conceived, the ovulation date was determined by the rat ovulation test and compared with the basal body temperature record.

At least 41 per cent of the conceptions took place before there was any change in temperature. Thirty-seven per cent were interpreted as occurring as the temperature was rising; 15 per cent of the subjects conceived when their temperatures were at the lowest point, and in 7 per cent conception took place after the rise.

Summary of Data

Identification Figure No.	Case No.	Cycle Days of Tempera- ture Rise	Concep- tion Day	Average Length of Menstrual Cycle	Post- Ovulatory Interval	Remarks
1	1	15-19	13	24	11	Coitus cycle day 12 and 13; conception before rise
	2	10-25	11	25	14	A.I.X.*; conception before rise

* A.I.X. is artificial insemination, anonymous donor.

† Inc. is incomplete temperature record.

‡ A.I. is artificial insemination.

In some cases there appeared a rise in temperature, followed by a drop and subsequent rise. When such double shifts occur it becomes difficult, if not impossible, to predict the time of ovulation on the basis of basal body temperature.

The rises in temperature were gradual in practically all instances, requiring several days for their completion. The shift from the low to the high point, in the majority of cases, averaged only 1 degree, with a range of from 3/5 to 1 2/5 degrees.

These observations indicate that the changes in basal body temperature in most instances are of such a nature that they do not permit an accurate timing of ovulation. It is accepted generally that ovulation is impending when the temperature is at its lowest point, rather than during its rise, which is rather variable. In this investigation at least 48 per cent of the conceptions took place before or after the change in temperature. From this fact alone it would appear that, in spite of a bimodal curve, a consistent temperature pattern is lack-

Two to fifteen days were required for the temperature change to be completed. An average of four and five-tenths days was required for the temperature to rise from its lowest to its highest point.

The average temperature shift from the low to the high point was 1 degree, with a range of from 3/5 to 1 2/5 degrees.

Conceptions occurred on cycle days 9 to 17, in cycles which averaged twenty-four to thirty-four days in length. Eighty-five per cent of the conceptions occurred between cycle days 10 to 14, inclusive. The postovulatory intervals in the months prior to the one in which conception took place averaged fourteen and seven-tenths days, with a range from eleven to seventeen days.

The use of the basal body temperature as a method for detecting the time of ovulation may serve as an aid in the treatment of infertility in women in about 45 per cent of the cases. It is not a satisfactory method for detecting the day of ovulation of all patients.

CHEMOSURGICAL TREATMENT OF CANCER OF THE SKIN

A Microscopically Controlled Method of Excision

FREDERIC E. MOHS, M.D.

Madison, Wis.

The term "chemosurgery" was coined to designate a newly developed method for the treatment of cancer. The most important feature of the method is the technic by which thorough microscopic control of excision may be attained. This microscopic control makes possible, in effect, the selective destruction of cancer with the resultant dual advantages of unprecedented reliability and conservatism. The use of the method is limited to accessible regions of the body because the procedure is carried out in stages.

The development of the method, both in the laboratory¹ and in the clinic,² has been described as has been the application of the method in the treatment of cancer of the lip,³ nose,⁴ ear,⁵ eyelid,⁶ face,⁷ extremities and trunk.⁸ The present article concerns the chemosurgical treatment of cancer of the skin except for the orificial cancers affecting the lips, vulva, penis and anus. The therapeutic results in a consecutive series of 814 cases in which the patients were observed for a period of three years or more are presented.

TECHNIC

In the chemosurgical treatment of cancer of the skin, the microscopic control of excision is accomplished by means of a process consisting of the following steps: (1) chemical fixation in situ of the tissues suspected of being cancerous by means of a paste containing zinc chloride, (2) excision of a layer of the fixed tissue, (3) location of the cancerous areas by systematic microscopic examination of the excised tissues, (4) further chemical treatment limited to the areas demonstrated to be cancerous and (5) repetition of the process until the cancer, including all its irregular extensions, has been entirely excised.

To illustrate the way in which the chemosurgical technic is carried out, there will be described the chemosurgical excision of a cancer of the temple (fig. 1A).

The lesion was first noticed seven years previously as a small, crusted ulcer on the left temple just lateral to the eyebrow. The patient had received no treatment except for the application of a caustic plaster by a "cancer quack." The lesion consisted of an irregular, indurated mass 4 cm. in diameter. The neoplasm protruded slightly but the main mass appeared to be below the level of the skin. It was fixed to the underlying bone and there was

an extension into the lateral part of the upper eyelid. The central part of the lesion was ulcerated.

After preparation with 0.03 Gm. of codeine and 0.65 Gm. of acetylsalicylic acid, dichloroacetic acid was applied to the skin which covered the peripheral portion of the neoplasm. This keratolytic chemical served to render the surface keratin permeable to the zinc chloride. The first application of the zinc chloride fixative⁹ was made in a depth of approximately 2 mm. The applied material was covered with a thin layer of cotton, and this in turn was covered with a layer of cotton on which petrolatum was spread to maintain a moisture-tight closure. The dressing was fastened in place with adhesive tape and the patient was instructed to take the analgesics mentioned previously as often as every three hours, as needed.

Fig. 1.—A, basal cell carcinoma of group D (average diameter 3 or more cm.). Starting seven years previously, the ulcerated mass had continued to enlarge though treated with caustic applications. The neoplasm was excised in six microscopically controlled stages by the chemosurgical technic (fig. 2). B, appearance of the lesion after separation of the final layer of fixed tissue. A small area of bone near the anterior edge is exposed. C, healed lesion. The patient is free of cancer after ten years.

On the next day a layer of tissue approximately 5 mm. thick was excised with a scalpel. Since the incision was carried through fixed tissue there was no pain or bleeding from this procedure. After the excision of this layer, the cancer was grossly visible as a white friable tissue. Therefore microscopic visualization was unnecessary at this stage and the fixative was reapplied to the entire area. A frozen section revealed the neoplasm to be a highly invasive basal cell carcinoma. The following day another layer of tissue was excised and again the entire area was seen to be cancerous by gross examination. Consequently, the fixative was again applied to the entire area.

On the third day, however, it was impossible to determine by gross examination how much of the lesion contained cancer. Therefore, the entire excised layer was divided into four specimens of convenient size. Frozen sections were immediately cut through the under surface of each of these specimens so that the entire area could be subjected to systematic microscopic examination. To aid in orientation, the edges of the specimens were marked with india ink and with merbromin, which coloring materials were retained throughout the procedure by which the tissues were frozen, cut, stained, cleared and mounted. The locations from which the specimens were removed were marked on the lesion with merbromin, the red color of which stood out well against the white fixed tissue. A map also was drawn on a pad of paper. By scanning the microscopic sections it was found that almost the entire area was cancerous (fig. 2A). The fixative paste was reapplied to all but the small area at the lower edge, which was demonstrated to be free of cancer.

On the next two days, the procedure was repeated and the area of cancer was found to decrease in size (figs. 2, B and C) and

on the following day, the entire area was free of cancer (fig 2D). Each application of the fixative was limited to the areas demonstrated to be cancerous. The most deeply situated portion of the cancer involved the periosteum of the bone of the orbital rim (fig. 2, C and D). Thus, the more deeply situated portions of the cancer were followed microscopically for four days after the cancer tissue became indiscernible to the naked eye. The

Fig. 2.—Maps showing locations of specimens removed on successive days from the lesion pictured in figure 1. Stippled areas represent cancer located by microscopic examination of frozen sections through the under surface of each specimen.

microscopic control made it possible to be radical in the excision of the anterior part of the lesion where the cancer extended deeply and to be conservative in the excision of the posterior part of the lesion where the cancer was more superficial.

The lesion was covered with petrolatum gauze for seven days, after which interval the final layer of fixed tissue was removed, revealing granulation tissue except in the region where the bone was exposed (fig. 1B). Another two weeks elapsed before the fixed bone separated, and the lesion was healed when the patient returned for a checkup one month later. The final scar was soft, smooth, pliable and almost the same color as the surrounding skin (fig. 1C). The patient was free of cancer after ten years.

As reported in the articles on the chemosurgical treatment of cancer in various locations, the time required for separation of the final layer of fixed tissue varies according to the tissues involved. Thus, while separation of the fixed tissue from most regions of the face requires about seven days, the period is only three days for the eyelids, four days for the lower lip and as much as ten days for the back. Apparently, the thicker the dermis, the longer the time required for separation of the fixed tissues.

Hemorrhage is not a problem except when one is working in the region of the large vessels, such as the common carotid artery or the jugular vein. Arteries such as the superficial temporal or the external maxillary vessels ordinarily do not bleed during separation of the fixed tissue. If there seems to be some likelihood that bleeding will occur, it is wise to place a suture-ligature around the vessel during the period of separation.

The amount of analgesic medication required for the control of the pain during the period of penetration of the fixative varies with the size and location of the lesion. Small lesions may be treated without the use of analgesics, but patients with large lesions in sensitive areas may require analgesics as potent as morphine.

For the technical details of the chemosurgical treatment of cancer in various anatomic sites, the reader is referred to previously published articles.

THERAPEUTIC RESULTS IN CASES OF BASAL CELL CARCINOMA OF THE SKIN

A total of 555 patients with basal cell carcinoma of the skin were chemosurgically treated during the eight year period ending Aug. 31, 1944. The extent of the lesions varied from early to extremely advanced and many would ordinarily be classed as inoperable. Over one third of the cancers were recurrent after previous surgical, radiation or caustic treatment. There was no instance of metastasis.

Three Year and Five Year End Results.—The 555 cases of basal cell carcinoma were divided into "indeterminate" and "determinate" groups, according to the

example of Martin, MacComb and Blady.¹⁰ The indeterminate group includes (1) the cases of patients who died of intercurrent disease without evidence of recurrence and (2) those who were lost from observation without recurrence. The determinate group is composed of (1) the cases of patients in whom unsuccessful results were obtained (the patients who died of cancer, who were lost from observation with cancer or who are living with cancer) and (2) the cases of patients in whom successful results were obtained (the patients who remained free of cancer for a period of three years or more). In the 458 cases of basal cell carcinoma in the determinate group the rate of cure after three years or more was 97.4 per cent (table 1).

TABLE 1.—End Results for Basal Cell Carcinoma of the Skin after Periods of Three Years and Five Years.*

	Three Year Period	Five Year Period
Total number of cases	555	398
Indeterminate group		
Patients dead from other causes without recurrence	78	87
Patients lost from observation without recurrence	19	20
Total number	97	107
Determinate group		
Total number	458	291
Unsuccessful results		
Patients dead, cancer present at time of death	9	8
Patients lost from observation with cancer	3	3
Patients living with cancer	0	0
Total number	12	11
Successful results		
Patients free from cancer for three years or more	446	
Patients free from cancer for five years or more		280
Three year end results		
Total number of cases with successful results divided by total number of determinate cases (446÷458)	97.4	
Five year end results		
Total number of cases with successful results divided by total number of determinate cases (280÷291)		96.2

*This series includes the cases of all patients with histologically proved basal cell carcinomas, both early and advanced, previously untreated and recurrent, who were admitted to the Chemosurgery Clinic from June 26, 1936, to Aug. 31, 1944, for the three-year group, and from June 26, 1936, to Aug. 31, 1944, for the five-year group.

In the five year period there was a total of 398 cases of basal cell carcinoma of the skin. The rate of cure in the 291 cases in the determinate group was 96.2 per cent (table 1).

Effect of Size of Lesion on Prognosis.—The 458 basal cell carcinomas in the determinate group in the three year period were placed in four groups according to the size of the primary lesion as measured at the initial examination of the lesion (table 2). The lesions in group A had an average diameter under 1 cm., group B, 1 to 2 cm., group C, 2 to 3 cm., and D, 3 cm. or more (figs. 1, 3 and 4).

As was to be expected, the prognosis was, to some extent, influenced by the size of the lesion (table 2). Thus, of the 393 lesions in groups A, B and C, there were only 3 unsuccessful results, while in the 65 patients with lesions in group D there were 9 unsuccessfully treated lesions. However, extensiveness per se is not a contraindicatory factor for the chemosurgical treatment of basal cell carcinoma of the skin unless the neoplasm has extended into some vital structure, such as the brain or large vessels such as the carotid artery or jugular vein. A number of patients with extremely advanced carcinomas were chemosurgically treated, and in most

10. Martin, H. E.; MacComb, W. S., and Blady, J. V.: Cancer of the Lip. *Ann. Surg.* 114:341 (Sept.) 1941.

of these successful results were obtained. However, in some, treatment was discontinued because of invasion through the skull into vital portions of the brain (3 patients); some signed their release (2 patients), while some had carcinomas which were found to be too advanced to justify complete removal in consideration of the patients' advanced age and poor general condition (7 patients).

Fig. 3.—A, basal cell carcinoma of group D. The lesion had begun twenty years previously and had repeatedly recurred after treatment with caustics and roentgen rays. Although relatively little cancer was discernible by gross examination, the entire abnormal area and some apparently normal tissues beyond were demonstrated to be invaded by cancer by means of three microscopically controlled excisions. B, granulation tissue following separation of the final layer of fixed tissue. C, healed lesion. The patient is free of cancer after four and one-half years.

Effect of Previous Treatment on Prognosis.—In the 458 cases in the determinate group in which basal cell carcinomas were chemosurgically excised, 155 of the lesions (33.6 per cent) had previously been unsuccessfully treated by surgical operation, roentgen rays, radium or caustics, either alone or in combination. Although it

TABLE 2.—Effect of Size of Basal Cell Carcinoma on Prognosis.

Group	Average Diameter, Cm.	Number of Lesions	Successful Results	
			Number	Percentage
A	Under 1	167	167	100
B	1-2	158	157	99.4
C	2-3	68	66	97.1
D	3 or more	65	56	86.1
All groups		458	446	97.4

was possible to salvage 145 (93.5 per cent) of the patients with recurrent lesions, the rate of cure was appreciably lower than the rate of cure of 99.3 per cent for the 355 cases in which the patients had not been previously treated.

The adverse effect of previous treatment on prognosis is due mainly to the delay occasioned by the ineffective treatment. The fact that 93.5 per cent of the patients with recurrent cancers were successfully treated by the chemosurgical method indicates that this method is particularly valuable for recurrent lesions.

Effect of Degree of Invasiveness on Prognosis.—While there is no formal division of basal cell carcinoma

into grades of malignancy, it is practical to designate their invasiveness as either "high" or "low." The histologic appearance of the highly invasive type is characterized by slender, poorly demarcated groups of carcinoma cells with an indefinite demarcation between them and the copious connective tissue stroma. In contrast, carcinoma with a low degree of invasiveness is composed of large, rounded clumps of basal cells, well demarcated from the surrounding relatively meager connective tissue stroma. Clinically, the highly invasive type is apt to show the erosion, ulceration and deep induration which are characteristic of the rodent ulcer (illustrated by figs. 1, 3 and 4), while the lesion of low invasiveness is apt to show the well defined outgrowing masses characteristic of the nodular type of basal cell carcinoma. Intergradations between these two distinct types are common.

Fig. 4.—A and B, basal cell carcinoma, group D. The lesion was of seven years' duration and had repeatedly recurred after twenty treatments with electrodesiccation and four treatments with radium. There was considerable atrophy, ulceration, crusting and indefinite induration, but the exact extent of the neoplasm was difficult to determine. The highly invasive basal cell carcinoma was excised in twelve microscopically controlled stages by the chemosurgical technic. C, granulation tissue after separation of the final layer of fixed tissue showing how much more extensive the neoplasm was than could be determined at the initial examination. In particular the extensions into the forehead and cheek regions were not foreseen. D, healed lesion. The uninvolved inferior border of the septum was preserved for use in the plastic reconstruction. The patient is free of cancer after five years.

In the 458 cases in the determinate group, 305 (66.6 per cent) were classified as highly invasive. In the cases in this group the rate of cure was 96.4 per cent. In contrast, in the 153 cases in which the carcinoma had a low degree of invasiveness, the rate of cure was 100 per cent. However, these figures are not to be taken to indicate that the chemosurgical technic is less strongly indicated in highly invasive lesions. Quite the opposite, the highly invasive recurrent, troublesome lesion is a prime indication for the chemosurgical technic because the microscopic control makes it possible to follow out each of the deeply permeating radicles which are characteristic of these lesions.

Effect of Site of Origin of Basal Cell Carcinomas on Prognosis.—The site of origin of basal cell carcinoma has some influence on the prognosis (table 3). The 222

TABLE 3.—Effect of Site of Origin of Basal Cell Carcinoma on Prognosis.

Nose	133	130	97.7
All Sites	458	446	97.4

lesions affecting the extremities, trunk, face and head were all successfully treated. The rates of cure for carcinoma affecting the ear, eyelid and nose were less than the foregoing largely because of the greater likelihood that the neoplasm would invade deeply into openings such as the ear canal, the orbit and the nasal cavity. Nevertheless, it is in these locations where complicated patterns of extension are apt to occur that chemosurgical treatment is particularly indicated.

THERAPEUTIC RESULTS IN CASES OF SQUAMOUS CELL CARCINOMA OF THE SKIN

A total of 259 squamous cell carcinomas of the skin were chemosurgically excised in the eight year period ending three years prior to this writing.

End Results After Three Years and Five Years.—The end results were calculated by the same means as were used in the section on basal cell carcinoma. In the three year period, successful results were obtained in 85.6 per cent of 222 cases in the determinate group (table 4). In the five year period, successful results were obtained in 84.4 per cent of 136 cases in the determinate group (table 4).

Five year end results		
Total number of cases with successful results divided by total number of determinate cases (115÷136)		84.4

*This series includes the cases of all patients with histologically proved squamous cell carcinomas, both early and advanced, previously untreated and recurrent, with or without metastases, who were admitted to the Chemosurgery Clinic from July 20, 1936 to Aug. 11, 1944 for the three year group, and from July 20, 1936 to Aug. 31, 1944 for the five year group.

Effect of Size of Lesion on Prognosis.—The squamous cell carcinomas were divided into four groups according to size: A, under 1 cm. in average diameter (fig. 5); B, 1 to 2 cm. (figs. 6 and 7); C, 2 to 3 cm., and D, over 3 cm.

The rate of cure of patients with lesions in groups A and B was extremely high (100 per cent and 95.1 per cent, respectively) while in patients with lesions in group C the rate of cure dropped to 86.6 per cent and in group D to 60.7 per cent (table 5). The main reason for the adverse influence of large size on prognosis was the greater incidence of metastasis associated with the large lesions. Thus, this complication was the cause of an unsuccessful result in 21 patients in whom the primary lesion was eradicated. In only 11 cases was it not feasible to eradicate the primary lesion. In the latter group the cause of failure was the involvement of vital portions

Fig. 5.—A, squamous cell carcinoma of group A (under 1 cm.). The growth was removed in two microscopically controlled stages by the chemosurgical technic. B, granulation tissue after separation of the final layer of fixed tissue. C, healed lesion. The patient was free of cancer when he died five years later.

of the brain in 2 cases, involvement of the large vessels of the neck in 1 case and such deep and extensive involvement in the remaining 8 cases that complete removal was not justifiable because of poor general health, advanced age or the presence of metastasis.

TABLE 5.—Effect of Size of Squamous Cell Carcinoma on Prognosis.

Group	Average Diameter, Cm.	Number of Lesions	Successful Results	
			Number	Percentage
A	Under 1	50	50	100
B	1-2	81	77	95.1
C	2-3	30	26	86.6
D	3 or more	61	37	60.7
All groups		222	190	85.6

While patients with large lesions have a distinctly poorer prognosis, it is not to be inferred that large size, in itself, is a contraindicatory factor as far as chemosurgical treatment is concerned. A considerable number of lesions which were incurable by ordinary surgical and radiation treatment were successfully treated by the chemosurgical method because of the facility with which the ramifying radicles of the advanced carcinoma could be followed out.

Effect of Previous Treatment on Prognosis.—In the 222 cases of squamous cell carcinoma in the determinate group in the three year period, 63 lesions (28.4 per cent) had recurred after previous unsuccessful treatment by surgical, radiation or caustic therapy. While it was possible to salvage 68.3 per cent of this group of recurrent lesions, this rate of cure was considerably below the rate of 92.5 per cent attained by the chemosurgical treatment of the 159 previously untreated lesions.

The adverse influence of previous treatment on prognosis is largely due to the delay occasioned by the use of the unsuccessful treatments. This delay increases the chance of metastasis and the possibility of invasion of vital structures in some cases, while in others the lesion becomes too extensive for eradication of the neoplasm to be practical. Previous therapy, per se, however, is not to be considered a contraindicatory factor as far as

chemosurgical treatment is concerned. Indeed, the most definite indication for chemosurgical treatment may be the lesion which has resisted other forms of therapy.

Effect of Histologic Grade of Malignancy on Prognosis.—Classification of the 222 squamous cell carcinoma

Fig. 6.—A, squamous cell carcinoma, group B. The cancer which had a grade of malignancy of 4, was removed in three microscopically controlled stages by the chemosurgical technic. B, healed lesion. The patient was free of cancer after six years.

nomas of the skin on the basis of Broders' four grades of malignancy revealed a strong correlation between histologic structure and prognosis (table 6). The higher proportion of unsuccessful results associated with carcinoma

TABLE 6.—Effect of Histologic Grade of Malignancy of Squamous Cell Carcinoma on Prognosis.

Grade	Number of Lesions	Successful Results	
		Number	Percentage
1	69	67	97.1
2	97	86	88.7
3	50	36	72
4	6	1	16.6

nomas with a higher grade of malignancy is due to the greater incidence of metastasis and the greater likelihood of invasion of vital structures exhibited by these lesions. A carcinoma which has a high degree of malignancy but which has not yet invaded a vital structure or metastasized has virtually the same prognosis when treated by the chemosurgical technic as a lesion of a lower grade of malignancy. Inasmuch as lesions with the higher grade of malignancy are much more apt to send out irregular, infiltrating extensions into the surrounding tissue, the microscopic control afforded by the chemosurgical technic is particularly advantageous in the treatment of these lesions.

Fig. 7.—A, squamous cell carcinoma, group B, of six months' duration. The growth was removed in three microscopically controlled stages by the chemosurgical technic. B, granulation tissue after removal of the final layer of fixed tissue. C, healed lesion. The patient is free of cancer after nine years.

Effect of Site of Origin of Squamous Cell Carcinoma on Prognosis.—The site of origin had only a minor effect upon the rate of cure of squamous cell carcinoma

(table 7). The lowest rate was for carcinoma of the ear, which is explained by the relatively high proportion of metastasis from lesions in this region and by the proximity to vital structures the invasion of which can render impossible a successful result. The next lowest rate of cure was for squamous cell carcinoma of the extremities and trunk. The low rate in this category is explained by the fact that a large proportion of these lesions affected the hand and fingers, which sites are notoriously unfavorable due to the high incidence of metastasis

TABLE 7.—Effect of Site of Origin of Squamous Cell Carcinoma on Prognosis.

Location	Number of Lesions	Successful Results	
		Number	Percentage
Ear	44	35	80
Extremities and trunk	45	38	84.4
Eyelids	17	16	94.1
Face and head	91	78	85.7
Nose	25	23	92
All sites	222	190	85.6

arising from the great amount of motion in these structures.

Effect of Metastasis on Prognosis.—In cases of squamous cell carcinoma of the skin, the most serious complication is metastasis. Thus, in the 222 cases in the determinate group in the three year period, there were 32 in which unsuccessful results were obtained, and in 27 (84.4 per cent) of these metastases occurred. Also indicative of the serious prognostic influence of metastasis was the fact that of the 29 patients in whom metastasis was present, only 2 (7 per cent) were successfully treated, whereas in the group of 193 patients without metastasis, 188 (97.4 per cent) were successfully treated. In the 27 patients in whom unsuccessful results were obtained due to the presence of metastasis, the primary lesion had been chemosurgically eradicated in every case as far as could be determined when the patient was last seen.

In 18 cases, resection of the metastatic nodes was attempted by members of the surgical staff, but in only 1 was a successful result obtained. One successful result also was obtained by the chemosurgical excision of a metastatic nodule in the inner canthal region secondary to a carcinoma on the nose. In a number of these cases, the nodes were conceded to be inoperable but were resected for the purpose of palliation. Several patients were given palliative roentgen therapy without noticeable benefit.

In several patients whose cases are included in this series the primary lesion was chemosurgically excised in the presence of inoperable metastases for the purpose of palliation.

COMMENT

The unprecedented reliability of the chemosurgical treatment of cancer is indicated by comparison with statistical results from other centers for cancer treatment. One of the best series, with respect to both statistical validity and also excellent therapeutic results, is that of Magnussen,¹¹ who reported on the results obtained in a series of 1,343 cases with the highly developed radiologic, surgical and electrosurgical technics employed at Radiumhemmet in Stockholm, Sweden. From his protocols it was determined that his three year rate of cure for carcinoma of the skin was 88 per cent in the three year period. In the present series of 814 cases, of which 680 were in the determinate group, the rate of cure was 93.6 per cent. This record was attained despite

11. Magnussen, A. H. W.: Skin Cancer: A Clinical Study with Special Reference to Radium Treatment, Acta radiol., 1935, supp. 22, p. 1.

the fact that a higher proportion of my cases were in the groups of the larger-sized lesions and despite the fact that more of my patients previously had been unsuccessfully treated. Another comparable series is that from the Norwegian Radium Hospital as reported by Poppe;¹² his study of 198 cases revealed a rate of cure in the three year period of 80 per cent. Another statistically adequate series is that reported by Warren, Simmons and Rea¹³ from the Huntington Hospital in Boston; they reported a rate of cure of 76 per cent in the five year period. The rate of cure in the present series of 577 cases in the five year period is 93.8 per cent. Some excellent results have been reported in the treatment of cancers falling in the realm of dermatology, as, for example, the series of Elliot and Welton.¹⁴ However, such series are made up, for the most part, of relatively small lesions, whereas the present series includes the cases of a large number of patients whom the dermatologist ordinarily would refer to a surgeon and it even includes a considerable number which ordinarily would be considered inoperable.

The reliability attained by the chemosurgical method does not depend on an excessively radical approach. Quite the opposite; the method is conservative since only 1 or 2 cm. beyond the actual level of carcinomatous invasion at any given point need be removed. In effect, the chemosurgical method, by virtue of the microscopic control, provides a selective means for the destruction of cancer tissue, although, of course, the fixative chemical itself has no selective action.

The reason why microscopic control of excision is necessary for the attainment of maximum reliability and conservatism is the great irregularity and unpredictability of the outlines of most carcinomas of the skin. This is particularly true of the more advanced and recurrent lesions, but it may also be true in the smaller lesions which have not received previous treatment. Frequently, there are found irregular outgrowths of cancer in tissues such as the perineurium, periosteum, perichondrium, lymphatics and embryologic fusion planes. Most of these outgrowths are not initially demonstrable, even by most careful clinical examination, and it is only by the systematic microscopic control of the chemosurgical technic that each of these extensions can be accurately followed out and eradicated.

Another advantage of the chemosurgical method is the virtual absence of operative mortality. This feature is particularly important in view of the advanced age and poor health of a large number of the patients with cancer of the skin. The 1 operative death in this series occurred after an attempt to remove a squamous cell carcinoma which extensively invaded the meninges and the brain in the temporal region.

A disadvantage of the chemosurgical method is that a certain amount of training and experience with the method is essential for the most favorable results. Essential, also, is a special clinic with facilities for the preparation of frozen sections and with the services of technical assistants trained in the handling of the specimens of fixed tissue.¹⁵ I believe that the microtechnical work should be done in or near the chemosurgical clinic.

because the sections should be examined by the operator himself. Another disadvantage is that in the treatment of extensive lesions, the technic is somewhat laborious and time-consuming for the operator and somewhat painful for the patient. However, these disadvantages are of small consequence in consideration of the fact that most of these advanced lesions would not be cured by any other means.

The fact that the chemosurgical method is useful in the treatment of a number of other accessible forms of cancer besides cancer of the skin and the fact that it is applicable to the treatment of certain noncancerous conditions such as precancerous dermatoses, benign neoplasms, radiation ulcers, certain forms of infection and gangrene,¹⁶ make it evident that the method has a rather wide field of application. Therefore, it would seem to be justifiable to recommend the establishment of chemosurgical clinics in each large center of population.

It might be well to mention that zinc chloride, the fixative used in the chemosurgical technic, has been used for over a hundred years in the treatment of cancer. It was used mostly by quacks and irregular practitioners, and there was never any thought of microscopic control. It cannot be too strongly emphasized that the microscopic control is the only unique and by far the most important feature of the chemosurgical method. Without this control, the use of chemicals for the destruction of cancer is completely without justification. A large proportion of the slender outgrowths from the main tumor mass are completely invisible to the naked eye, so that, without microscopic control, the treatment of cancer by caustic chemicals would be unreliable and excessively mutilating.

SUMMARY AND CONCLUSIONS

The chemosurgical technic as used in the microscopically controlled excision of cancer of the skin is described and the therapeutic results in a series of 814 cases are analyzed.

The reliability of the method is indicated by the unusually high proportion of successful results. Thus, for basal cell carcinoma, successful results were attained in 97.4 per cent of the 458 determinative cases observed for three years or more and in 96.2 per cent of 291 cases observed for five years or more. For squamous cell carcinoma, the rate of cure was 85.6 per cent for the 222 cases in the three year period and 84.4 per cent for the 136 cases in the five year group. These results were attained despite the fact that many of the cancers were far advanced and over one third had recurred after previous surgical, radiation or caustic treatment.

The method is conservative, since only 1 or 2 mm. of tissue is removed beyond the point of actual carcinomatous invasion.

The reliability of the method is due to the microscopic control which makes it possible to follow out the irregular and unpredictable extensions from the main tumor mass. The conservatism is also a result of the microscopic control, because this control makes it possible to be only as radical as required by the actual demonstrated extent of the cancer.

There was only 1 death attributable to the chemosurgical procedure in this series of 814 cases.

OVERTREATMENT DERMATITIS IN DERMATITIS VENENATA DUE TO PLANTS

G. B. UNDERWOOD, M.D., and L. EDWARD GAUL, M.D.

Evansville, Ind.

Acute cutaneous symptoms can cause a psychic upset to the same degree as that observed when other organs of the body become ill, perhaps even more so, because the skin is an organ of special sense and gives rise to multiple sensory stimuli. A person at an outing may win all the prizes, but that night he can be pacing the floor, so mentally harassed that he calls out for relief from symptoms of dermatitis due to plants. The itching and burning can so torment him that he is not responsible for his actions. Patients thus afflicted will apply remedy after remedy, blindly groping for relief. In view of this panic-like state which may seize persons with acute cutaneous symptoms, it is their privilege that remedies for the skin in the family medicine chest and purchased by them be reasonably safe. Evidence will be presented that many of these remedies are not safe, some of them dangerous to use. In our series of 202 cases of dermatitis venenata due to plants, 152 patients had applied a remedy or remedies that caused acute complications, and certain chemicals in these changed acute dermatitis into chronic. An era of advanced therapeutics is marred by dermatologic treatments which caused 75 per cent of these patients to be improperly and unwisely managed.¹

The past treatment patch test² was used routinely in this investigation. Each patient was asked to bring in the remedies that he had used. Checking over the bags, baskets, satchels and boxes laden with preparations for the skin proved to us the urgent need for a renaissance in dermatologic therapeutics. The entire gamut of vehicles was jumbled together: tinctures, lotions, creams, powders and salves. The colors of the chemicals transformed the skin into weird patterns as if it had been prepared for an Indian war dance. A barbarous custom is being imitated by dermatologic treatments. The containers of some of the medicaments had all but disintegrated. Often the stoppers had lost their threads, were mere parchment shells or had become soft and pitted, their decomposition products admixed with the preparation. Some of the tinctures showed a slimy flocculation. The lotions looked like old white shoe polish bottles and smelled of phenol. A few were marked inflammable. One bottle, when the stopper which the chemicals had cemented into place was pried loose, popped, and the contents, looking angry and menacing, spurted forth. After this experience we smelled the remedies from the side first. The powders were over everything. Some were caked or lumpy; others had attacked the sifting holes or plugged them up. The salves were colored green, blue, pink, red, brown, black or yellow. They slithered around in the jars or tins with the usual outside smearing. Their consistency was variable; some were uniform, others granulated, speckled or marbled. The ingredients did not affect glass, but the tin containers and plastic tops were honeycombed, pitted and discolored. No flies were seen; these ointments were too potent. One foul salve was more than twenty years old. The patient, an elderly lady, spoke warmly of its healing powers and how she had carefully saved it by changing

to a new tin each time the old one disintegrated. She was shocked at the patch test reaction to this "healing balm." People will save salves like hoarding treasures and use them over and over again in spite of their age and state of decomposition. The conclusion from examining these assortments of dermatologic remedies was that their ingredients were highly active chemicals with irreversible tendencies proceeding until something was affected or destroyed. We saw their disastrous effects in the cases of dermatitis venenata due to plants.

CLINICAL DATA ON THE CASES OF DERMATITIS VENENATA DUE TO PLANTS

DISTRIBUTION OF PATIENTS BY SEX AND DECADE

There were 31 patients in the first decade, 13 males and 18 females; 32 in the second, 10 males and 22 females; 41 in the third, 17 males and 24 females; 36 in the fourth, 21 males and 15 females; 16 in the fifth, 7 males and 9 females; 28 in the sixth, 13 males and 15 females; 13 in the seventh, 5 males and 8 females; and in the eighth, 3 males and 2 females. Eighty-five per cent of the patients were over 10 years old.

DISTRIBUTION OF PATIENTS BY SEX AND OCCUPATION

Excluding children under 10, of the 76 males, 12 were farmers and of the 95 females, 69 were housewives. The American home in this locality is a major cause of cutaneous disease, especially for the female. The incidence of dermatitis acquired in the yard—weeds, grasses, trees, shrubs, flowers, produce gardens and tending poultry—merely augments the incidence acquired inside the house from cosmetics, cleaners, polishes, insecticides, shoes, clothing and the family medicine chest. Only 9 per cent of the patients traced their dermatitis to avocational pursuits, which places dermatitis venenata due to plants in a class of dermatoses acquired accidentally while performing some necessary duty.

INCIDENCE OF ATOPY AND DERMATITIS VENENATA

There were 90 patients to whom dermatitis venenata due to plants was a new experience; 24 of these were children. One hundred and twelve patients had had previous attacks. A family history of atopy was obtained in 3 cases and a personal history in 5 cases. These data are in accord with those of Zisserman³ and Knowles and co-workers.⁴

EXPOSURE AND ETIOLOGY

One hundred and forty-two patients associated a time and place with their attack of dermatitis venenata. Some of them knew the particular plant. In 60 cases the time and place of exposure were unknown, and of the 60 patients 16 were children. The rural patients frequently spoke of "dew poisoning." Dew as it falls is innocuous but it is reasonable to expect that saturation of a plant at various stages of maturity will affect the adhesiveness, perhaps the solubility of the irritant and provide a more penetrating exposure.

A. Types of Dermatoses and Plants Responsible.—

1. The primary lesions were streaked and the etiology was confirmed by finding the Rhus in the collections of plants. There were only 40 cases in this group.

2. The primary lesions in this group were discrete and crusted, numbering from one to many. Clinically, they resembled Bockhart's impetigo, acne varioliformis, impetigo contagiosa or ecthyma. The lay diagnosis was summer, fall or touch sores. The 20 patients, 12 of

4. Knowles, F. C.; Decker, H. B.; Pratt, A. G., and Clarke, J. A., Jr.: Susceptibility of Allergic and Nonallergic Persons to Rhus Toxicodendron, Arch. Dermat. & Syph. **38**: 773 (Nov.) 1938.

whom were children, were observed during the seeding time of the grasses, particularly crab grass. Patch tests with crab grass reproduced the primary lesion. Tests at a later date were negative in result, and it seems that at a certain stage of maturity, the grass causes reaction, whereas before or after this time the irritant has been changed or is no longer present.

3. These lesions were diffuse and resembled neurodermatitis. Distributed among 29 cases were seven reactions to dog fennel, two to Indian mallow, three to tumble grass, two to hollyhock, ten to ragweed, three to goldenrod and two to horse nettle. Patch tests gave characteristic flaring reactions, indicating a high degree of sensitization. The symptoms in this group were the most severe. In the remaining 113 cases the etiology was not determined. This does not mean that reactions were not obtained, but they failed to reproduce the primary lesion and were thus considered secondary contributors. If the causative plant was tested, the behavior of its reaction pattern proved diagnostic; the selective specificity was remarkable. This explains why persons will be in contact with plants for weeks or months, but when the plant to which they are sensitive matures, then their dermatitis appears. (There were 142 cases in this group.)

B. *Detection of Plants Responsible.*—The plant oleo-resin extracts⁵ were purchased for contact testing. In spite of an obvious clinical diagnosis, the reactions in the first 6 cases were negative to all the extracts. Gradually, reactions appeared to Rhus and sumac. The twenty-third and fourth patients reacted so violently, the entire back a bullous dermatitis, that these extracts had to be removed from the test series. A total of 83 patients were tested with consistent negative results. We had to conclude that the extracts were of little diagnostic value. To prove this further, another series of 92 patients were tested with the dog fennel extract compared to the fresh plant: blossom, leaf and stem. A few patients reacted to the leaf and stem but all reacted to the blossom, which permits classifying this plant as a primary irritant. It grows abundantly, especially in farm yards. All tests to the dog fennel extract were negative in result. Reluctantly, we again had to furnish paper bags for a friend or relative of the patient to collect the fresh plants from the known or probable area of exposure.

ACUTE CUTANEOUS AND SYSTEMIC COMPLICATIONS FROM DERMATOLOGIC CHEMICALS

Deeply entrenched in the minds of people is the fear of infection. This specter haunts most channels of public information. The dictum is preached that a break in the skin permits the invasion of pathogenic organisms unless an antiseptic is applied forthwith. Laymen do not differentiate an incised wound from the breaking up of the protective barriers of the skin by contactants. The result is that all cutaneous signs, irrespective of etiology and even symptoms, are touched up with antiseptics. The chemist and bacteriologist have supplied reams of data on the test tube performances of the myriads of antiseptics, but their toxicity—their incubation period on normal and abnormal skin—has been overlooked, often wrongly interpreted as infection. As a result, all the mercurial antiseptics at least need reconsideration.

A. THE PRIMARY CUTANEOUS OVERTREATMENT REACTION

1. *History.*—The history was always the same among the overtreated patients. Cutaneous symptoms appeared

after an exposure to some plant. Itching and burning often mean infection to laymen, so as a rule these were given the "once over" with an antiseptic; and as the signs appeared, treatment was started in earnest. If a proprietary is said to help itching or to heal, people will use it for any skin condition that itches or any sign they wish to heal. A review of the indications of the remedies brought in for past-treatment patch testing disclosed that few of them were advised for dermatitis venenata due to plants. In their choice of remedies, these patients were guided by hearsay evidence and pharmacologic definitions on labels. A preparation was placed in high public esteem if it was antiseptic, germicidal, antipruritic, soothing and healing: "Nothing could beat a five in one job." One patient with the help of his wife carried in a bushel basket of remedies for the skin. Ten of them belonged to relatives and friends who knew from personal experience the salve that would get rid of the trouble.

2. *Location.*—The area of skin most frequently involved by a plant contactant became the eventual site of the primary overtreatment reaction; namely, the hand, forearm, legs, feet, face and neck.

3. *Duration.*—Dermatitis due to plants is of short duration; hours to one or several days. The overtreatment reaction was always two weeks, commonly three or four weeks and sometimes several months.

4. *Symptoms.*—Seizures of violent itching are observed from plant contactants. The symptoms from overtreatment are commonly mild or often absent. The area of skin seems stunned, as if its innervation were cut off. The systemic symptoms, however, take precedent. These patients described themselves as upset. They had not slept the way they should, their appetites were poor and their elimination sluggish. They were depressed and apprehensive about the condition of their skin.

5. *Signs.*—The area of involved skin suggests a local shocklike state. It is frequently cool to palpation, especially in the early stages. Edema is present throughout; the erythema indolent as if the capillaries had lost their powers of constriction. Vesiculation masses the area and is closely packed. Bullae are common and some hemorrhage is the rule. In the later stages, pustules appear and are a cardinal sign of overtreatment. Zoning was present to varying degrees in many of the cases. A central zone was made up of edema, erythema, vesicles and bullae with or without some hemorrhage. An intermediate zone showed little reaction, and a peripheral zone was characterized mainly by closely packed vesicles.

6. *Incubation Period.*—This is the unknown and probably the most significant factor in our knowledge of the chemistry, pharmacology, dosage and clinical indications of cutaneous therapeutic chemicals. Toxicity from drugs given orally and parenterally is constantly looked for; physicians have been on the alert, but toxicity from dermatologic chemicals has been for the most part unrecognized or called something else.

(a) *Simple Therapeutic Chemicals:* Simple therapeutic chemicals were encountered most commonly among the mercurial antiseptics. The incubation period followed a sequence and was conditioned by the number of exposures, the duration of the exposure and the chemical formula of the therapeutic agent. The determinate factor was the integrity of the protective barriers of the skin; namely the pH, lipid film and the horny mantle. To illustrate the importance of these barriers, 82 postoperative patients were given patch tests⁶ with

5. Graham Laboratories, Willow Lane, Dallas, Texas.

6. We were enabled by Dr. Paul Crimm to test 40 patients from Boehne Tuberculosis Hospital.

three to six different mercurial antiseptics. The patients had been exposed to "merthiolate" at least once and some of them two or three times. They never had had any skin trouble and the surgical incisions healed promptly. All patch tests were negative in result. When the protective barriers had been broken up by a plant irritant, the application of "merthiolate" to this injured skin induced the primary overtreatment reaction and systemic signs of sensitization. Patch tests performed on 187 patients showed that 66 of them had become sensitive, an incidence of 35 per cent. The time factor of the incubation period varied from hours to several days or a week or longer. The history of the patients with a short incubation period revealed past exposures to "merthiolate," especially for treatment of previous attacks of dermatitis contact. These patients noted an immediate flare up—less than twenty-four hours—on applying "merthiolate" to the area affected by dermatitis venenata due to plants, and their reactions to patch tests appeared early, hours to one day. The history in the cases with a long incubation period—a week or more

the splitting off of the mercury in "merthiolate" or they may reflect mercurial exposures from amalgam fillings or past treatments. The single ring of "merthiolate" may have conditioned the reactions to thiosalicylic acid which were grouped with aqueous "merthiolate" seventeen times and the tincture four times. We are unable to explain the single reactions. Perhaps, a history of all therapeutic chemical exposures in these patients, oral, parenteral and topical, might disclose an explanation. We believe that dermatologic chemicals having a single ring are good epidermal penetrants and probably should be so classified.

The reactions to ethyl aminobenzoate always disclosed a present treatment contact. This chemical ranks with "merthiolate" in sensitizing powers. An opportunity was presented to perform intradermal tests with a solution of procaine 1 per cent, in 6 cases of sensitivity to ethyl amino-benzoate after the local and systemic signs began to subside. The tests were done on the flexor surface of the forearm. In 4 cases a flare response of the entire flexor surface of the arm appeared. In the remaining 2

—revealed past exposures of normal skin to "merthiolate," insect bites and trivial traumas. The application of "merthiolate" to the area currently affected by dermatitis did not produce a flare-up for a week or more. Patch tests before the flare-up were usually negative in result, whereas after the flare-up they may be positive and frequently are, if "merthiolate" was reapplied to the area of flare-up. There was evidence in these cases that the incubation period at the site of exposure to "merthiolate" was reflected in the time for the patch tests to become positive in result; the longer the incubation period the greater the likelihood of delayed reactions in patch tests. The appearance of pustules after exposure to "merthiolate" almost permits predicting a positive reaction in a patch test.

The incidence of reactions to therapeutic chemicals in patch tests is shown in table 1. "Merthiolate" had the highest exposure ratio, which explains why it should show the greatest incidence of reactions. It seems that this chemical carries two sensitizing factors; the mercury ion and the single ring structure. The reactions to mercuric bichloride were probably conditioned by

cases, flare reactions about 4 cm. in diameter were observed. At the point of injection, a ring of erythema persisted several days and the area involved by pustulation. The duration of the sensitivity to ethyl amino-benzoate is not known, but it is possible that the wide use of this chemical on the skin can predispose to violent systemic reactions when procaine might be used as a local anesthetic. Goodman⁷ presented data that in the procaine group of local anesthetics, the sensitivity was directed to the substituted aniline base, para-amino-benzoyl.

Among the patients reacting to ammoniated mercury, 6, by chance, were observed with a faint erythema spreading peripherally from the site of treatment. The diameters varied from 4 to 18 cm. Patch tests on the arm elicited a reaction of about 1 plus, but in the area of erythema it was 4 plus. Several days later the reaction on the arm became 4 plus. We may have observed the spreading of sensitization through the skin by way of the superficial nerve or vascular structures. Perhaps

the designation toxicity would be better than sensitization. Ammoniated mercury produced no single reactions but grouped with mercuric chloride and "merthiolate" to a sufficient degree to prompt common ion participation.

While statistically the reactions to "mercesin" (amyltricrosols and orthohydroxyphenylmercuric chloride) and nitro mersol ("metaphen") are insignificant; we believe, if their incidence of exposure approached that of "merthiolate," these antiseptics would behave similarly. The degree of dilution of the mercurial makes little difference because, as the repetition and duration of the cutaneous exposure increase, the likelihood of sensitization also increase. It is common to obtain reactions to mercury in dilutions of 1:1,000,000. The group reactions would suggest that one chemical in sensitizing the skin predisposes a reaction to other related chemicals. The chemicals producing reactions in patch tests always had an immediate past or present therapeutic contact. This high specificity was remarkable. It supports the conclusions of Rostenberg and Kanof⁸ and interestingly adds emphasis to the "cutaneous memory" observations of Sulzberger.⁹ If the memory of the skin for treatment chemicals is ever analyzed, the renaissance in dermatology will come about almost over night. Many textbooks will become historical references. It is clear, also, that the tendency of manufacturers to copy formulas is causing a "cross firing" to occur on the skin. The chemical in one formula produces the exposure; the same chemical in another formula initiates the sensitization reaction. The latter is blamed, but in reality the former is the real culprit.

These data are in agreement with previous investigations in this field. The skin was exposed to simple chemicals which on fulfillment of the incubation requirements caused sensitization in some of the cases. It is, we believe, highly significant that the chemicals studied: "orthoform,"¹⁰ "mesothan"¹¹ (methoxymethyl salicylate), paraphenylendiamine,¹² phenylhydrazine,¹³ dinitrochlorobenzene,¹⁴ trinitrophenol and butesin,¹⁵ were all single ring compounds. Adding emphasis are the investigations that the sensitizing substance in Rhus is also a single ring compound.¹⁶ From our data, we conclude that the repetition and duration of exposure to certain therapeutic chemicals will cause the incidence of generalized sensitization to increase. A present flaw in dermatology is the treatment of dermatitis caused by a chemical contactant with therapeutic chemicals having comparable irritating or sensitizing powers.

(b). Dermatologic Proprieties and Prescriptions: Reactions to past-treatment patch tests were obtained to 62 proprietaries and 226 prescriptions. When it was

possible to identify the latter, they were as a rule some proprietary devoid of all identification except the admonition, "Rub into the affected area as often as necessary." Usually it was one, sometimes two and rarely three chemicals in the proprietary that caused reactions. These chemicals had produced a flare-up of the dermatitis and, as often as not, the prescription contained the same chemicals. This abuse is widespread and is comparable to prescribing a laxative containing phenolphthalein to a patient having a phenolphthalein dermatitis. An observation which has become almost a therapeutic law with us is that if a particular remedy seemed to help at first, the continued use of it will sooner or later cause an exacerbation of the dermatitis. The overtreated patients with recurrent attacks of dermatitis due to plants pointed out in their collections preparation after preparation which for the first attack worked wonders but when used for a second attack made the dermatitis worse. The period of time that the remedy was credited as helping was also the incubation time for certain chemicals in the formula. When the latter was satisfied, the next exposure produced a sensitization reaction. The foregoing statement presupposes that the dermatitis venenata involved the same area of skin at the time of the second attack. Pages of the following example could be cited.

A patient had dermatitis venenata involving the forearms two years ago. "Mazon" a combination of phenolic substances and organic mercury c. was applied and the dermatitis promptly cleared. This year the patient had another attack; again the forearms were involved. "Mazon" was used for one week, when suddenly the dermatitis flared. The exposure 2 years ago met the incubation requirements of the mercury salicylate in "Mazon," and its second application proved to be the sensitizing dose.

7. Etiology: The past treatment patch test investigations have brought out the critical importance of the protective barriers of the skin. A chemical outside these barriers has its toxic properties in a different category than when inside where it can affect living tissue. The evidence in the cases of overtreatment offers little support for the concept that these patients were allergic, had an idiosyncrasy or were hypersensitive. The primary overtreatment reaction was basically a manifestation of the toxicity of certain therapeutic chemicals. From our data, the chemicals in table 2, are unsafe for self treatment of dermatitis venenata due to plants.

8. Care and Management.—The cases of dermatitis venenata due to plants were not observed at the time of exposure to the plant irritant. The properly treated patients were seen one to three days, even a week after their exposure, and the improperly treated patients a week to several weeks or months. Therefore, it seemed foolish to do anything directed at the plant irritant. It had already struck. We observed the symptoms which relayed the location and warned the patient of danger. We noted the signs—edema, erythema, vesicles, bullae and weeping—measures which the skin takes to prevent absorption and dissemination to neutralize and eject the irritant. The control of symptoms in these cases presented no problem. We told the patients to scratch as often and as much as they desired. Many of them heaved a sigh of relief and quizzically countered, "I am glad you said that because I couldn't help doing it anyway." We have never observed a skin which we could prove had been injured by scratching or a dermatitis that had been made worse by scratching.

(a). The Primary Overtreatment Reaction: On inspection the lesions appeared grossly infected. They

swarmed with the usual skin bacterial flora. Where the bacteria flourished, many different antiseptics had been and were residing. The deeper the antiseptics penetrated the living skin the greater the weeping, dripping and pustulation. The latter were considered drainage manifestations.

TABLE 2.—*Chemicals Unsafe for Self Treatment of Dermatitis Venenata Due to Plants**

Tars and Derivatives	Metallic Compounds	Plant Products	Alcohols
Butesin pterate... 2	Ammoniated mercury... 15	Absinthin, Menthol, Echinacea, Calendula... 4	Solution formaldehyde... 3
Ethyl aminobenzoate... 24	Copper sulfate... 1	Grindelia... 4

Resorcin... 3	Orthochloro-mercuriphenol... 4		
Salicylic acid... 8	Potassium mercuric iodide... 3		
Tars, decolorized... 14	Phenylmercurio nitrate... 6		

* The number after each chemical indicates the number of patients that showed positive reaction in patch tests. It seems incredible that plant extracts were ever indicated for therapy of plant dermatoses.

† Two proprietaries showed reactions, but the separate ingredients were negative. Apparently oxidation of hydroxyquinoline can produce a sensitizer.

‡ Proprietaries containing these chemicals had been in the household a long time. We suspect that ageing produced a sensitizer in them.

§ This chemical was in the proprietaries which were essentially Whitfield's ointment. The proprietary elicited a positive reaction but the separate ingredients a negative one. The preparations were all over a year old. We suspected an oxidation or reaction product with salicylic acid.

(1) Drainage phase.—The drainage phase was encouraged by saline compresses or poultices (boiled oatmeal or cream of wheat). The drainage was most profuse in the central zone, and in this region healing appeared first. As the pustules finished draining, bleeding often occurred in their bases which soon formed dry crusts. Healing was now rapid in and around the old pustules. Drainage was promoted twelve to twenty-four hours. Then the affected area was bathed with water and covered with cotton. If weeping and pustules reappeared, poultices were again applied, and this procedure was continued until the area remained dry.

(2) Drying phase.—The peripheral area where the uninvolved meets the involved skin takes the longest to heal. Frequently minute pustules appear before the healing ensues. During this phase the skin is kept covered with cotton, which has a splinting action, and this is enhanced by leaving in place scabs, crusts and scales. When regeneration and repair have proceeded far enough exfoliation appears; then the cotton protection is removed.

(3) Erythema of involution.—After exfoliation a faint erythema usually persists several weeks or even a month. The appearance throughout this area of pinpoint vesicles and pustules has been a constant observation. We interpret these signs as the regeneration stage of the ducts of the cutaneous glands. Dermatitis naturally disrupts the duct system, and the secretions of the cutaneous glands play an important part in freeing the skin of irritants. It is a rule in medicine that obstruction of free drainage leads to formation of pus and that the removal of the obstruction causes the former to resolve. This rule is a vital part of the care and management of the skin.
